# Using First-Order Logic to Reason about Submodule Construction ${ }^{1}$ 

Gregor v. Bochmann<br>School of Information Technology and Engineering (SITE), University of Ottawa, Canada bochmann@site.uottawa.ca<br>A shorter version of this paper was included in the proceedings of the IFIP international conference on Formal Techniques for Distributed Systems (FMOODS/FORTE), 2009

#### Abstract

We consider the following problem: For a system consisting of two components, the behavior of one component is known as well as the desired global behavior. What should be the behavior of the second component such that the behavior of the composition of the two conforms to the desired behavior ? - This problem has been called "submodule construction" or "equation solving"; and in the context of supervisory control, it is the problem of designing a suitable controller (second component) which controls a given system to be controlled (first component). Solutions to this problem have been described in the context of various specification formalisms and various conformance relations. This paper presents a new formulation of this problem and its solution in first-order logic. It is also shown how the solutions for submodule construction in various specification formalisms can be derived from the solution in logic. The simple proof of correctness for the logic solution is then used to justify the particular forms of solutions in the different specification formalisms, such as (a) synchronous rendezvous at several interfaces, and (b) interleaved rendezvous (labeled transition systems).

## 1. Introduction

In automata theory, the notion of constructing a product machine S from two given finite state machines $\mathrm{M}_{\mathrm{A}}$ and $\mathrm{M}_{\mathrm{B}}$, written $\mathrm{M}=\mathrm{M}_{\mathrm{A}} \times \mathrm{M}_{\mathrm{B}}$, is a well-known concept (see Figure 1(a)). This notion is very important in practice since complex systems are usually constructed as a composition of smaller subsystems, and the behavior of the overall system is in many cases equal to the composition obtained by calculating the product of the behaviors of the two subsystems. Here we consider the inverse operation, called "equation solving" or "submodule construction": Given the composed system M and one of the components $\mathrm{M}_{\mathrm{A}}$, what should be the behavior of the second component $\mathrm{M}_{\mathrm{B}}$ such that the composition of these two components $\mathrm{M}_{\mathrm{A}}$ and $\mathrm{M}_{\mathrm{B}}$ will exhibit a behavior equal to M . That is, we are looking for the value of X

[^0]which is the solution to the equation $\mathrm{M}_{\mathrm{A}} \mathrm{x} \quad \mathrm{X}=\mathrm{M}$ (see Figure 1(b)). This problem is an analogy of integer division, which provides the solution to the equation $\mathrm{N} 1 * \mathrm{X}=$ N for integer values N 1 and N . In integer arithmetic, there is in general no exact solution to this equation; therefore integer division provides the largest integer which multiplied with N1 is smaller than N. Similarly, in the case of equation solving for machine composition, we are looking for the most general machine X which composed with $\mathrm{M}_{\mathrm{A}}$ satisfies some conformance relation in respect to M . In the simplest case, this conformance relation is trace inclusion.

Fig. 1. (a) two communicating components; (b) submodule construction problem
A first paper of 1980 [1] (see also [2]) gives a solution to this problem for the case where the machine behavior is described in terms of labeled transition systems (LTS) which communicate with one another by interleaved rendezvous interactions (see also [3] for a more formal treatment). This work was later extended to the cases where the behavior of the machines is described in CSP [4] (with behavioral equivalence as conformance relation) [5], by finite state machines (FSM) communicating through message queues [6], by input/output automata (IOA) [7, 8, 9] ([7] considers bisimulation as conformance relation), and by synchronous finite state machines [10, 11]. The case of extended state machine models including state variables and assertions about input and output parameters has also been studied [12]. The problem has also been formulated for databases using relational algebra [13].

One application of this submodule construction method was considered in the context of the design of communication protocols, where the components $M_{A}$ and $M_{B}$ may represent two protocol entities that communicate with one another [2]. Later it was recognized that this method could also be useful for the design of protocol converters in communication gateways [15, 16], and for the selection of test cases for testing a module in a context [17].

Independently, the same problem was identified in control theory for discrete event systems [18] as the problem of finding a controller for a given system to be controlled. In this context, the specification $\mathrm{M}_{\mathrm{A}}$ of the system to be controlled is given, as well as the specification of certain properties that the overall system, including the controller, should satisfy. If these properties are described by M, and the behavior of the controller is X , then we are looking for the behavior of X such that the equation $M_{A} x \quad X=M$ is satisfied. Solutions to this problem are described in [19] using a specification formalism of labeled transition systems where a distinction of input and output is made (interactions of the system to be controlled may be controllable (which corresponds to output generated by the controller) or uncontrollable (which corresponds to input to the controller). This specification formalism seems to be equivalent to input/output automata (IOA) [20].

In some private discussions, Nina Yevtushenko pointed out that the formulas that describe the solutions of the equations for synchronous and interleaving automata, as described in [11] and [1], respectively, have a quite similar structure. Later, when
listening to a talk on stochastic relational databases by Cory Butz, I noticed that the same kind of equation solving problem can be formulated in the context of relational databases, and that the solution has again a quite similar structure. I have argued [13, 9] that the problem of equation solving in relational databases is a generalization of the problem for synchronous and interleaving automata, and that also a solution for IOA can be derived from this more general problem. During the discussion after the presentation of my paper [9] at the FORTE conference, the question was raised whether this equation solving problem could also be formulated within the context of first-order logic.

The purpose of this paper is to show that, in fact, the equation solving (or submodule construction) problem can be formulated in logic. It turns out that (a) a solution with a structure similar to the solutions mentioned above exists, and (b) a proof of the correctness of this solution is quite simple, apparently much simpler than the existing proofs of correctness for the solutions in the contexts mentioned above. We show in this paper how the solutions for submodule construction in different contexts can be derived from the general solution in the logic context. The proof of correctness from the logic context can therefore be used to justify the particular forms of solutions in the contexts of different specification formalisms. We consider in this paper the context of communicating system components using (a) synchronous rendezvous at several interfaces, or (b) interleaved rendezvous (that is, labeled transition systems). Other contexts are considered in [32], such as synchronous (I/O) automata with complete or partial behavior specifications, interleaving IOA with complete or partial behavior specifications, and finite state machines with queued communication, as well as relational algebra for databases. These contexts include much of the previous work mentioned above and also some not so common modeling approaches.

The paper is structured as follows: The next section presents the problem of equation solving in the general context of first-order logic. The main concepts and equations are established which are then referenced in the subsequent sections. In Section 3, the submodule construction problem is introduced in the context of modular system design where the overall system is composed out of several components and the behavior of one of the components is to be found. A modeling framework for synchronous communication between all the components is introduced. Section 4 shows how this modeling framework can be used to model interleaving semantics, as used by labeled transition systems (LTS). Section 5 presents the conclusions.

## 2. Equation solving in the logic context

### 2.1. The logic context

We use in this section first-order logic with typed variables. We consider a universe with three variables $X_{A}, X_{B}$, and $X_{C}$ that may take values from three domains $D_{A}, D_{B}$ and $\mathrm{D}_{\mathrm{C}}$, respectively. These domains may be infinite. Therefore, the set of possible
value assignments to the variables is $U=D_{A} \times D_{B} \times D_{C}$. We write $x_{A}, x_{B}$, and $x_{C}$ for possible values of the variables $\mathrm{X}_{\mathrm{A}}, \mathrm{X}_{\mathrm{B}}$, and $\mathrm{X}_{\mathrm{C}}$, respectively.

We are interested in relationships between values of different variables. For instance, we may consider a relation $\mathrm{R} \subset \mathrm{D}_{\mathrm{A}} \times \mathrm{D}_{\mathrm{B}}$ which is a subset of pairs $<\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}$ $>$ of values of the variables $X_{A}$ and $X_{B}$. We also use predicates to characterize sets. For instance, the relation $R$ may be characterized by a predicate $C\left(x_{A}, x_{B}\right)$ which is true exactly for those pairs $<\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}>$ that are in R .

### 2.2. The equation solving problem

In the following, we are interested in three relations $\mathrm{R}_{\mathrm{A}} \subset \mathrm{D}_{\mathrm{B}} \times \mathrm{D}_{\mathrm{C}}, \mathrm{R}_{\mathrm{B}} \subset \mathrm{D}_{\mathrm{A}} \times \mathrm{D}_{\mathrm{C}}$ and $\mathrm{R}_{\mathrm{C}} \subset \mathrm{D}_{\mathrm{A}} \times \mathrm{D}_{\mathrm{B}}$. We write $\mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right), \mathrm{C}_{\mathrm{B}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)$, and $\mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)$ for their respective characterizing predicates. We consider the following proposition which relates these three relations:

$$
\left.\left.\forall<\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}>\in \mathrm{U}:<\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}>\in \mathrm{R}_{\mathrm{A}} \wedge<\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right\rangle \in \mathrm{R}_{\mathrm{B}} \Rightarrow<\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right\rangle \in \mathrm{R}_{\mathrm{C}} \quad\left(1^{\mathrm{Rel}}\right)
$$

This proposition may be equivalently rewritten in terms of the predicates as follows:

$$
\begin{equation*}
\forall<\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}>\in \mathrm{U}: \mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \mathrm{C}_{\mathrm{B}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right) \Rightarrow \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right) \tag{Pred}
\end{equation*}
$$

The problem of equation solving is the following: We assume that $R_{A}$ and $R_{C}$ are given. What are the properties of relation $R_{B}$ that ensure that proposition (1) is satisfied? - We would like to find a maximal solution $R_{B}{ }^{\text {max }}$ to this problem, that is, $R_{B}{ }^{\text {max }}$ together with $R_{A}$ and $R_{C}$ would satisfy (1), but any larger $R_{B}{ }^{\prime} \supset R_{B}{ }^{\text {max }}$ would not satisfy this proposition.

### 2.3. The maximal solution

Starting from ( $1^{\text {Pred }}$ ), it is easy to see that the following predicate characterizes the maximal solution:

$$
\begin{equation*}
\mathrm{C}_{\mathrm{B}}^{\max }\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)=\forall \mathrm{x}_{\mathrm{B}} \in \mathrm{D}_{\mathrm{B}}: \quad \mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \Rightarrow \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right) \tag{2}
\end{equation*}
$$

The right side of this definition can be equivalently transformed in several steps as follows:

$$
\begin{array}{ll}
\forall \mathrm{x}_{\mathrm{B}} \in \mathrm{D}_{\mathrm{B}}: & \neg \mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \vee \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right) \\
\forall \mathrm{x}_{\mathrm{B}} \in \mathrm{D}_{\mathrm{B}}: & \neg\left(\mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \neg \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)\right) \\
\neg \exists \mathrm{x}_{\mathrm{B}} \in \mathrm{D}_{\mathrm{B}}: \mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \neg \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)
\end{array}
$$

which leads to the following equivalent expression for the maximal solution:

$$
\begin{equation*}
\mathrm{C}_{\mathrm{B}}^{\max }\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)=\neg \exists \mathrm{x}_{\mathrm{B}} \in \mathrm{D}_{\mathrm{B}}: \mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \neg \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right) \tag{3}
\end{equation*}
$$

### 2.4. The realized subset of $\mathbf{R}_{C}$

We note that in general not all pairs $<x_{A}, x_{B}>\in R_{C}$ could be "realized" by $R_{A}$ and $\mathrm{R}_{\mathrm{B}}{ }^{\max }$.
Definition: We say that a pair $<x_{A}, x_{B}>\in R_{C}$ is realizable by $R_{A}$ and $R_{B}$ if there exist a value $x_{C} \in D_{C}$ such that $\left\langle x_{B}, x_{C}\right\rangle \in R_{A}$ and $\left.<x_{A}, x_{C}\right\rangle \in R_{B}$.
We call the subset of $R_{C}$ that is realisable by $R_{A}$ and $R_{B}{ }^{\text {max }}$ the maximally realisable subset of $\mathrm{R}_{\mathrm{C}}$ (or "product"), written $\mathrm{R}_{\mathrm{C}}{ }^{\text {prod }}$. We therefore have

$$
\begin{equation*}
<x_{A}, x_{B}>\in R_{C}{ }^{\text {prod }} \text { iff } \exists x_{C} \in D_{C}:<x_{B}, x_{C}>\in R_{A} \wedge<x_{A}, x_{C}>\in R_{B}^{\max } \tag{4}
\end{equation*}
$$

### 2.5. The reduced maximal solution

We consider the relation $R_{B}{ }^{\text {incompatible }}$ characterized by the following predicate:

$$
\mathrm{C}_{\mathrm{B}}^{\text {incompatible }}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)=\neg \exists \mathrm{x}_{\mathrm{B}} \in \mathrm{D}_{\mathrm{B}}: \mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)
$$

Lemma: There is no $\left.<x_{A}, x_{B}\right\rangle \in R_{C}$ that is realizable by $R_{A}$ and $R_{B}{ }^{\text {incompatible }}$.
Proof: Let us assume that there is a pair $\left\langle x_{A}, x_{B}\right\rangle \in R_{C}$ that is realizable by $R_{A}$ and $R_{B}{ }^{\text {incompatible }}$. According to the definition of "realizable", this implies that there is a $x_{C}$ $\in \mathrm{D}_{\mathrm{C}}$ such that $\left\langle\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right\rangle \in \mathrm{R}_{\mathrm{A}}$ and $\left\langle\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right\rangle \in \mathrm{R}_{\mathrm{B}}{ }^{\text {incompatible }}$. Now, the definition of $R_{B}{ }^{\text {incompatible }}$ implies that there is no $x^{\prime}{ }_{B} \in D_{B}$ such that $C_{A}\left(x^{\prime}{ }_{B}, x_{C}\right) \wedge C_{C}\left(x_{A}, x^{\prime}{ }_{B}\right)$. However, this is a contradiction, since $\mathrm{x}_{\mathrm{B}}$ satisfies this condition for $\mathrm{x}_{\mathrm{B}}{ }^{\prime}$.

We conclude from the lemma above that those pairs $<x_{A}, x_{C}>$ of $R_{B}{ }^{\text {max }}$ that are in $R_{B}{ }^{\text {incompatible }}$ do not contribute to the realization of $\mathrm{R}_{C}{ }^{\text {prod }}$. We therefore may eliminate from the solution $R_{B}{ }^{\text {max }}$ all pairs in $R_{B}{ }^{\text {incompatible }}$ and still obtain the same set $R_{C}{ }^{\text {prod }}$ of realizable pairs $\left\langle\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right\rangle$. We call this the reduced maximal solution to the equation solving problem. It is characterized by the following predicate:

$$
\begin{align*}
\mathrm{C}_{\mathrm{B}}^{\mathrm{red}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)= & \left(\exists \mathrm{x}_{\mathrm{B}} \in \mathrm{D}_{\mathrm{B}}: \mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)\right) \wedge \\
& \left(\neg \exists \mathrm{x}_{\mathrm{B}} \in \mathrm{D}_{\mathrm{B}}: \mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \neg \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)\right) \tag{5}
\end{align*}
$$

### 2.6. Example

$\mathrm{D}_{\mathrm{A}}=\left\{\mathrm{a}_{1}, \mathrm{a}_{2}\right\} ; \mathrm{D}_{\mathrm{B}}=\left\{\mathrm{b}_{1}, \mathrm{~b}_{2}, \mathrm{~b}_{3}\right\} ; \mathrm{D}_{\mathrm{C}}=\left\{\mathrm{c}_{1}, \mathrm{c}_{2}, \mathrm{c}_{3}, \mathrm{c}_{4}\right\} ;$
$\left.\left.\left.\mathrm{R}_{\mathrm{A}}=\left\{\left\langle\mathrm{b}_{1}, \mathrm{c}_{1}\right\rangle,<\mathrm{b}_{2}, \mathrm{c}_{2}\right\rangle,<\mathrm{b}_{1}, \mathrm{c}_{3}\right\rangle,\left\langle\mathrm{b}_{2}, \mathrm{c}_{3}\right\rangle,<\mathrm{b}_{3}, \mathrm{c}_{3}\right\rangle\right\} ;$
$\mathrm{R}_{\mathrm{C}}=\left\{<\mathrm{a}_{1}, \mathrm{~b}_{1}>,<\mathrm{a}_{2}, \mathrm{~b}_{2}>,<\mathrm{a}_{1}, \mathrm{~b}_{3}>\right\} ;$
The relation corresponding to the predicate $\neg \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)$ is the complement of $\mathrm{R}_{\mathrm{C}}$ in respect to the set of all tuplets in $D_{A} \times D_{B}$, written $\neg R_{C}$. The set of all tuplets in $D_{A} \times$ $D_{B}$ is also sometimes called the "chaos" over $D_{A} \times D_{B}$, written Chaos ${ }_{A \times B}$. We have Chaos $\left.\left.\left.\left.\left.\left._{\text {A×B }}=\left\{<a_{1}, \mathrm{~b}_{1}\right\rangle,<\mathrm{a}_{2}, \mathrm{~b}_{2}\right\rangle,<\mathrm{a}_{1}, \mathrm{~b}_{3}\right\rangle,<\mathrm{a}_{1}, \mathrm{~b}_{2}\right\rangle,<\mathrm{a}_{2}, \mathrm{~b}_{1}\right\rangle,<\mathrm{a}_{2}, \mathrm{~b}_{3}\right\rangle\right\}$, where the last three tuplets are in $\neg \mathrm{R}_{\mathrm{C}}$.

Using Formula (3), we obtain

$$
\begin{aligned}
& \mathrm{R}_{\mathrm{B}}^{\max }=\text { Chaos }_{\mathrm{A} \times \mathrm{C}} \backslash\left\{\left\langle\mathrm{a}_{1}, \mathrm{c}_{2}\right\rangle,<\mathrm{a}_{2}, \mathrm{c}_{1}>,<\mathrm{a}_{1}, \mathrm{c}_{3}>,<\mathrm{a}_{2}, \mathrm{c}_{3}>\right\} \\
= & \left\{<\mathrm{a}_{1}, \mathrm{c}_{1}>,<\mathrm{a}_{2}, \mathrm{c}_{2}>,<\mathrm{a}_{1}, \mathrm{c}_{4}>,<\mathrm{a}_{2}, \mathrm{c}_{4}>\right\}
\end{aligned}
$$

where "\" is the set subtraction operator.
We have $\left.\left.R_{C}^{\text {prod }}=\left\{<a_{1}, b_{1}\right\rangle,<a_{2}, b_{2}\right\rangle\right\}$ which is a subset of $R_{C}$.
We note that the tuplets $\left.<a_{1}, c_{3}\right\rangle$ and $\left.<a_{2}, c_{3}\right\rangle$ are in $R_{B}{ }^{\text {incompatible }}$, and the reduced maximal solution is $\mathrm{R}_{\mathrm{B}}{ }^{\text {red }}=\left\{\left\langle\mathrm{a}_{1}, \mathrm{c}_{1}\right\rangle,\left\langle\mathrm{a}_{2}, \mathrm{c}_{2}\right\rangle\right\}$.

## 3. Submodule construction for synchronous systems

### 3.1. Modeling systems consisting of several components

State machines are often used as models for reactive systems that interact with their environment. Often one considers a system model which is the composition of several state machines. Therefore a state machine is normally a component within a system, it interacts with other components of the system and possibly also with the environment of the system; or the state machine represents the interactions of the whole system with its environment.

A system component has one or more interfaces. An interface is a location where interactions with the environment of the component take place. Each interface i is associated with a domain $I_{i}$; the elements of $I_{i}$ are the possible interactions that may take place at that interface during a given time unit. We write $\mathrm{x}_{\mathrm{i}}{ }^{(t)}$ for the interaction that takes place at interface $i$ at time unit $t$. Clearly, $x_{i}^{(t)} \in I_{i}$ for all $t$. We write $x_{i}$ for a sequence of interactions at interface i over a certain time period. We write $I_{i} *$ for the set of all sequences that can be formed by concatenating interactions from the domain $\mathrm{I}_{\mathrm{i}}$. We have $\mathrm{x}_{\mathrm{i}} \in \mathrm{I}_{\mathrm{i}}{ }^{*}$.

We assume trace semantics for specification of the dynamic behaviour of a system, that is, the dynamic behavior of a system $M$ is defined in terms of the set of possible execution histories that could occur during the execution of the component. For a system with $n$ interfaces $i(i=1, \ldots, n)$, an execution history consists of a tuplet $<x_{1}, x_{2}, \ldots x_{n}>$ where $x_{i}(i=1, \ldots, n)$ is the sequence of interactions that occurred at interface i during the execution history. We therefore assume that the specification S of the dynamic behavior of M is given in the form of a (normally infinite) set of such tuplets. As in Section 2, instead of talking about the set S of tuplets, one may also talk about the predicate C that characterizes this set.

Let us assume that the system consists of a certain number of components (subsystems) $\mathrm{C}_{\mathrm{j}}(\mathrm{j}=1, \ldots \mathrm{~m})$, each connected to a certain number of interfaces. For instance $\mathrm{C}_{1}$ may be connected to interfaces $\mathrm{i}=1,3$ and 6 ; and its behaviour predicate, therefore, will be of the form $\mathrm{C}_{1}\left(\mathrm{x}_{1}, \mathrm{x}_{3}, \mathrm{x}_{6}\right)$. Let us assume that the system has performed synchronous interactions over t time units and the execution history $\mathrm{eh}=<$ $\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots \mathrm{x}_{\mathrm{n}}>$ has been observed. Since all components were involved in this execution, the behaviour predicates of all components must be true for the interface interaction sequences $\mathrm{x}_{\mathrm{i}}$ in eh.

We now ask the question: What could be the interactions $\mathrm{x}_{\mathrm{i}}^{(\mathrm{t}+1)}$ at the interfaces ( $\mathrm{i}=1, \ldots, \mathrm{n}$ ) during the next time unit $(\mathrm{t}+1)$. These interactions must satisfy the condition that the extended interaction sequences including that time unit, $x_{i}{ }^{\prime}=x_{i}$ concatenated-with $\mathrm{x}_{\mathrm{i}}^{(t+1)}$, should also satisfy the behaviour predicates of all the
components. This means that all components must be ready to engage in the interactions $\mathrm{x}_{\mathrm{i}}{ }^{(\mathrm{t}+1)}$ at those interfaces to which they are connected. In other words, there is a kind of global rendezvous between all the components to agree on a set of interactions $\mathrm{X}_{\mathrm{i}}^{(t+1)}$ at the interfaces that are agreeable to all component. This also means that any resulting execution history will satisfy all component behaviour predicates; in other words, the behaviour predicate of a composition of several components is the conjunction of the behaviour predicates of all participating components.

We note that the definition of this kind of synchronous rendezvous occurring simultaneously at several interfaces is a concept that would be difficult to be implemented in a distributed context. It is not clear whether this is a concept of practical importance, however, we think that it exhibits a theoretical simplicity that makes it interesting. Other more practical communication paradigms are discussed in the subsequent sections.

Besides composition, there is another important operation for describing the behaviour of a system consisting of several components. This is the hiding of an interface that is not visible from a certain perspective. Let us consider a system configuration consisting of several components and $n$ interfaces $i(i=1, \ldots, n)$. We assume that the dynamic behaviour of the system is characterized by the predicate $C\left(x_{1}, x_{2}, \ldots x_{n}\right)$. When one of the interfaces (say $i$ ) is hidden, we obtain a visible behaviour which only involves the non-hidden interfaces. We use the notation "hide ${ }^{(s y n)}{ }_{i}\left(C\left(x_{1}, x_{2}, \ldots x_{n}\right)\right.$ " to represent the predicate of this behaviour. As discussed in [23], this predicate has the following form:

$$
\begin{aligned}
& <\mathrm{x}_{1}, \ldots, \mathrm{x}_{\mathrm{i}-1}, \mathrm{x}_{\mathrm{i}+1}, \ldots, \mathrm{x}_{\mathrm{n}}>\in \operatorname{hide}_{\mathrm{i}}^{(\mathrm{syn})}\left(\mathrm{C}\left(\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots \mathrm{x}_{\mathrm{n}}\right)\right) \\
& \quad \text { iff } \exists \mathrm{x}_{\mathrm{i}} \in \mathrm{I}_{\mathrm{i}}^{*}:<\mathrm{x}_{1}, \ldots, \mathrm{x}_{\mathrm{i}-1}, \mathrm{x}_{\mathrm{i}}, \mathrm{x}_{\mathrm{i}+1}, \ldots, \mathrm{x}_{\mathrm{n}}>\in \mathrm{C}\left(\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots \mathrm{x}_{\mathrm{n}}\right)
\end{aligned}
$$

### 3.2. Submodule construction

We now consider a system configuration containing two components $M_{A}$ and $M_{B}$ as shown in Figure 2(a). Since the sequences at the three interfaces are constrained by the behaviour of the two components, we have the following predicate that characterizes the set of all possible execution histories of this system:

$$
\forall<\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}>\in \mathrm{U}: \quad \mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \mathrm{C}_{\mathrm{B}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)
$$

where $\mathrm{U}=\mathrm{I}_{A} * \times \mathrm{I}_{\mathrm{B}} * \times \mathrm{I}_{\mathrm{C}} *$ is the universal set of execution sequences for a system architecture as shown in Figure 2(a).

(a)

(b)

Fig. 2. Two components $M_{A}$ and $M_{B}$; (b) also showing the desired overall behavior $M_{C}$
Let us now assume that the system consisting of the composition of the two components $M_{A}$ and $M_{B}$ is supposed to behave like a system $M_{C}$ characterized by the
predicate $\mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)$, as shown in Figure 2(b). Then we have the following requirement:

$$
\forall<\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}>\in \mathrm{U}: \mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \mathrm{C}_{\mathrm{B}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)=\mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)
$$

If we suppose that the behavior defined by $C_{C}\left(x_{A}, x_{B}\right)$ represents a safety requirement, that is, all execution histories generated by the two components $M_{A}$ and $M_{B}$ must satisfy $\mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)$, then we have the requirement:

$$
\forall<\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}>\in \mathrm{U}: \quad \mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \mathrm{C}_{\mathrm{B}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right) \Rightarrow \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)
$$

This formula is identical to Equation ( $\left.1^{\text {Pred }}\right)$ if we assume that the domains $D_{i}$ of Section 2 are sets of interaction sequences, namely $D_{i}=I_{i}^{*}($ for $i=A, B$ and $C)$.

The equation solving problem introduced in Section 2 becomes, in the context of interacting state machines, the following "submodule construction problem". We assume a system structure as shown in Figure 2(b). If the specification of $M_{A}$ is given in the form of $\mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right)$, as well as the safety requirement $\mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)$ for the overall system, what is the most relaxed requirement for the dynamic behaviour of machine $\mathrm{M}_{\mathrm{B}}$ ?

Since the proposition $\left(1^{\text {syn }}\right)$ is identical to ( $1^{\text {Pred }}$ ), we can use Formula (3) to obtain the most general behaviour of $\mathrm{M}_{\mathrm{B}}$ that satisfies ( $\left.1^{\text {syn }}\right)$. Using the hiding operator discussed in Section 3.1, we may rewrite Formula (3) as follows:

$$
\mathrm{C}_{\mathrm{B}}^{\max }\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)=\neg \operatorname{hide}^{(\mathrm{syn})}{ }_{\mathrm{B}}\left(\mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \neg \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)\right)
$$

We note that the negation can also be expressed by the complement in respect to the corresponding chaos behaviour, as in the Formula ( $3^{\text {RelAlg }}$ ) of Section 2.7. This leads to the following:

$$
\mathrm{C}_{\mathrm{B}}{ }^{\max }\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)=\mathrm{I}_{\mathrm{A}} * \times \mathrm{I}_{\mathrm{C}} * \backslash \operatorname{hide}^{(\mathrm{syn})}{ }_{\mathrm{B}}\left(\left(\mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge\left(\mathrm{I}_{\mathrm{A}} * \times \mathrm{I}_{\mathrm{B}} * \backslash \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)\right)\right)\left(3^{\mathrm{syn}}\right)\right.
$$

It is important to note that the operators used in Formula ( $3^{\text {syn }}$ ) can be evaluated algorithmically if the infinite sets of sequences defined by $\mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right)$ and $\mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)$ are regular sets, that is, are defined by a state machine with a finite number of states. The number of states of the machine representing the composition of two machines is smaller or equal to the product of the number of states of the two machines. The complement is straightforward to calculate in the case of deterministic state machines and can be realized by complementing the accepting and non-accepting states. Unfortunately, the hiding operator introduces in general non-determinism and the resulting non-deterministic behaviour description must be transformed into a deterministic description which is a problem of exponential complexity (see for instance [24]). We conclude that the complexity of the sub-module construction problem for regular state machines is in general exponential.

The considerations concerning the realizability of all the sequences defined by $\mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)$ and the reduced maximal solution $\mathrm{C}_{\mathrm{B}}{ }^{\text {red }}$ are identical to what was discussed in Section 2. We note that one would normally be interested in the reduced maximal solution for the component $M_{B}$ which is given by the following formula:

$$
\begin{align*}
\mathrm{C}_{\mathrm{B}}{ }^{\text {red }}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right) & =\operatorname{hide}^{(\mathrm{syn})}{ }_{\mathrm{B}}\left(\mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)\right) \\
& \backslash \operatorname{hide}^{(\mathrm{syn})}{ }_{\mathrm{B}}\left(\left(\mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge\left(\mathrm{I}_{\mathrm{A}}^{*} \times \mathrm{I}_{\mathrm{B}} * \backslash \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)\right)\right)\right. \tag{syn}
\end{align*}
$$

### 3.3. Examples

We present here two examples which are very similar to the example of Section 2.6. If we take the variable values $\mathrm{a}_{\mathrm{i}}, \mathrm{b}_{\mathrm{j}}$, and $\mathrm{c}_{\mathrm{k}}$ of Section 2.6 as the possible interactions at the interfaces $\mathrm{I}_{\mathrm{A}}, \mathrm{I}_{\mathrm{B}}$ and $\mathrm{I}_{\mathrm{C}}$, respectively, and impose no constraints on the order in which these interactions may take place, we obtain state diagrams for $M_{A}$ and $M_{C}$ with a single state having a transition for each tuplet in the respective relation $\mathrm{R}_{\mathrm{A}}$ or $\mathrm{R}_{\mathrm{C}}$ defined in Section 2.6. For example, for $\mathrm{M}_{\mathrm{C}}$ we obtain the state diagram of Figure 3(a), and similarly for $\mathrm{M}_{\mathrm{A}}$. This example is isomorph to the example of Section 2.6 and yields as reduced maximal solution a machine that allows the synchronous transitions $<\mathrm{a}_{1}, \mathrm{c}_{1}>$ and $<\mathrm{a}_{2}, \mathrm{c}_{2}>$ in an arbitrary order.

To make this example a bit more interesting, we consider now that the behaviour of $\mathrm{M}_{\mathrm{C}}$ is given by the state diagram of Figure 3(b) which means that synchronous interaction tuplets $<\mathrm{a}_{1}, \mathrm{~b}_{1}>$ and $<\mathrm{a}_{2}, \mathrm{~b}_{2}>$ must alternate and one or more $<\mathrm{a}_{1}, \mathrm{~b}_{3}>$ may be inserted after a $<a_{1}, b_{1}>$. In this case we obtain the reduced maximal solution shown in Figure 3(c).

Fig. 3. (a) behavior of a synchronous machine $M_{C}$ corresponding to the example of Section 2.6; (b) modified behavior of machine $\mathrm{M}_{\mathrm{C}}$; (c) reduced maximal solution for the modified behavior of $\mathrm{M}_{\mathrm{C}}$

## 4. Submodule construction for labeled transition systems

### 4.1. Modeling interleaving semantics

In this modeling framework, we also have rendezvous interactions at interfaces, but interleaving semantics is assumed, which means that at most one interaction (on a single interface) may occur during each time unit. We use in the following the same modelling framework used for synchronous machines, but introduce the following changes:

- We allow an interface to have the value null during a given time unit, which means that no interaction takes place at this interface during this time unit.
- In a system of several components with n interfaces, a possible execution history $<$ $\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots \mathrm{x}_{\mathrm{n}}>$ must satisfy the following constraint, called interleaving constraint: $\operatorname{IC}\left(x_{1}, x_{2}, \ldots x_{n}\right)=$ for all $t: x_{i}^{(t)} \in I_{i}$ implies $x_{j}^{(t)}=$ null for all $\mathrm{j} \neq \mathrm{i}$.
Any execution history $h=\left\langle x_{1}, x_{2}, \ldots x_{n}\right\rangle$ that satisfies the interleaving constraint defines a linear (time) order for the (non-null) interactions at the interfaces. We write seq(h) for this sequence and call it the execution sequence corresponding to
$h$ ．For execution sequences over $n$ interfaces，as above，we have $\operatorname{seq}(h) \in\left(I_{1} \cup I_{2}\right.$ $\left.\ldots \cup \mathrm{I}_{\mathrm{n}}\right)^{*}$ ．Normally，the semantics of labelled transition systems is described in terms of these（finite and infinite）execution sequences and the possibilities of blocking after finite sequences．We will continue using the model of separate interaction sequences $x_{i}$ at the different interfaces，as introduced for synchronous communication；we thus obtain a uniform framework for treating systems with both types of communication，synchronous and interleaving．
Definition（Equivalence of execution histories）：Since only the execution sequences count for the semantics of labelled transition systems，we say that two execution sequences $h_{1}$ and $h_{2}$ are equivalent，written $h_{1} \cong h_{2}$ ，if they define the same execution sequence，that is， $\operatorname{seq}\left(h_{1}\right)=\operatorname{seq}\left(h_{2}\right)$ ．

This corresponds to the so－called stuttering equivalence between execution sequences that contain at certain time units null－interactions at all interfaces．Clearly， we assume that any predicate defining the behaviour of a given system component has the same value for equivalent execution histories；the value should only depend on the corresponding execution sequence．

The notion of equivalence between execution histories leads to a slightly modified definition of the hiding operator as follows：

```
\(<x_{1}, \ldots, x_{i-1}, x_{i+1}, \ldots, x_{n}>\in \operatorname{hide}^{(\mathrm{LTS})}{ }_{i}\left(C\left(x_{1}, x_{2}, \ldots x_{n}\right)\right)\)
    iff \(\operatorname{IC}\left(x_{1}, \ldots, x_{i-1}, x_{i+1}, \ldots, x_{n}\right)\)
    \(\wedge \exists<x_{1}{ }^{〔}, \ldots, x_{i-1}{ }^{〔}, x_{i}{ }^{〔}, x_{i+1}{ }^{〔}, \ldots, x_{n}{ }^{‘}>:\left(\operatorname{IC}\left(x_{1}{ }^{〔}, \ldots, x_{i-1}{ }^{〔}, x_{i}{ }^{〔}, x_{i+1}{ }^{〔}, \ldots, x_{n}{ }^{`}\right)\right.\)
        \(\left.\left.\wedge<x_{1}{ }^{‘}, \ldots, x_{i-1}{ }^{\prime}, x_{i+1}{ }^{`}, \ldots, x_{n}{ }^{`}\right\rangle \cong<x_{1}, \ldots, x_{i-1}, x_{i+1}, \ldots, x_{n}\right\rangle\)
        \(\left.\wedge<x_{1}{ }^{`}, \ldots, x_{i-1}{ }^{〔}, x_{i}{ }^{`}, x_{i+1}{ }^{`}, \ldots, x_{n}{ }^{`}>\in C\left(x_{1}, x_{2}, \ldots x_{n}\right)\right)\)
```

## 4．2．Submodule construction

Due to the interleaving constraints and the equivalence between execution histories， we have the following modified equations．Equation（ $1^{\text {syn }}$ ）becomes：

$$
\forall<\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}>\in \mathrm{U}: \operatorname{IC}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \mathrm{C}_{\mathrm{B}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right) \Rightarrow \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right) \quad\left(1^{\mathrm{LTS}}\right)
$$

Equation（2）becomes：

$$
\begin{aligned}
& \mathrm{C}_{\mathrm{B}}{ }^{\max }\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)=\mathrm{IC}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \forall<\mathrm{x}_{\mathrm{A}}{ }^{`}, \mathrm{x}_{\mathrm{B}}{ }^{`}, \mathrm{x}_{\mathrm{C}}{ }^{‘}>\in \mathrm{U} \text { : }
\end{aligned}
$$

This definition of $C_{B}{ }^{\max }$ says that an execution history at the interfaces $I_{A}$ and $I_{C}$ is an allowed behavior for component $\mathrm{M}_{\mathrm{B}}$ if for all global execution histories $<\mathrm{x}_{\mathrm{A}}{ }^{\text {}}, \mathrm{x}_{\mathrm{B}}{ }^{\text {}}, \mathrm{x}_{\mathrm{C}}{ }^{\text {}}$ $>$ that have an equivalent behavior for $M_{B}$ ，the satisfaction of $C_{A}$ leads to the satisfaction of $\mathrm{C}_{\mathrm{A}}$ ．This modification to Equation（2）is introduced because the specification of the behavior for $\mathrm{M}_{\mathrm{B}}$ can only restrain the possible execution sequences of the component，but has no impact on which of the equivalent execution histories would be realized in collaboration with the other system components and the environment．

Using a similar demonstration as for Equation（3）in Section 2，it is easy to see that Equation $\left(2^{\text {LTS }}\right)$ is equivalent to

$$
\begin{aligned}
& \mathrm{C}_{\mathrm{B}}{ }^{\text {max }}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)=\mathrm{IC}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \neg \exists<\mathrm{x}_{\mathrm{A}}{ }^{`}, \mathrm{x}_{\mathrm{B}}{ }^{`}, \mathrm{x}_{\mathrm{C}}{ }^{`}>\in \mathrm{U} \text { : }
\end{aligned}
$$

Using the definition of the hiding operator above, this can be rewritten in the form

$$
\mathrm{C}_{\mathrm{B}}{ }^{\max }\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)=\mathrm{IC}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \neg \operatorname{hide}^{(\mathrm{as})}{ }_{\mathrm{B}}\left(\mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \neg \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)\right) \quad\left(3^{\mathrm{LTS}}\right)
$$

Using a similar demonstration as for Equation (5) in Section 2, we can show that the reduced maximal solution is given by the formula

$$
\begin{align*}
& \mathrm{C}_{\mathrm{B}}{ }^{\text {red }}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{C}}\right)=\operatorname{hide}^{(\mathrm{LTS})}{ }_{\mathrm{B}}\left(\mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)\right. \\
& \wedge \neg \operatorname{hide}^{(\mathrm{LTS})_{B}}\left(\mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \neg \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)\right) \tag{LTS}
\end{align*}
$$

This solution was presented (using a different notation) in [1], which was the first paper on submodule construction to our knowledge. We note that this formula is the same as ( $\left.5{ }^{\text {syn }}\right)$, except that a different hiding operator is used.

Like in the case of synchronous machines, these solutions may be evaluated algorithmically when the specifications of $\mathrm{C}_{\mathrm{A}}$ and $\mathrm{C}_{\mathrm{C}}$ are given in the form of regular languages (finite state machines).

### 4.3. Example

An example is shown in Figure 4. State diagrams representing the behaviour of $M_{A}$ and $M_{C}$ are shown (solid boxes) in Figure 4(a) and (b). The state diagram for $M_{C}$ also shows the Fail ( F ) state (a non-accepting state) and as well as the non-allowed transitions (dotted arrows). The behaviour of $\left(\mathrm{C}_{\mathrm{A}}\left(\mathrm{x}_{\mathrm{B}}, \mathrm{x}_{\mathrm{C}}\right) \wedge \mathrm{C}_{\mathrm{C}}\left(\mathrm{x}_{\mathrm{A}}, \mathrm{x}_{\mathrm{B}}\right)\right)$ is shown in Figure 4(c); it represents the composition of the two state machines $M_{A}$ and $M_{C}$. The diagram is incomplete, since transitions from a composed state where $M_{C}$ is in the Fail state are not shown.

Fig. 4. $(a, b)$ State diagrams representing the behavior of $M_{A}$ and $M_{C}$

Fig. 4. (c) Behavior of the composition of $M_{A}$ and $M_{C}$; (d) the same after hiding interactions $b_{1}$ and $b_{2}$ and determination

Figure 4(d) shows the state diagram obtained from Figure 4(c) after the following two steps: (a) hiding the interactions $b_{1}$ and $b_{1}$ at the interface $I_{B}$, and (b) transforming the resulting non-deterministic machine into an equivalent deterministic one. Each state of the deterministic machine represent a subset of the states of the original non-deterministic machine, namely those that could be reached through transitions including the hidden ones (see for instance [24] for details). Since Equation ( $5^{\text {LTS }}$ ) only considers execution sequences that can be generated jointly by $\mathrm{M}_{\mathrm{A}}$ and $\mathrm{M}_{\mathrm{C}}$ and that can not reach the Fail state of $\mathrm{M}_{\mathrm{A}}$, we do not need to explore the transitions for the resulting deterministic machine from any state that includes in its subset a state pair for which $\mathrm{M}_{\mathrm{C}}$ is in the Fail state. We conclude that Equation (5 ${ }^{\text {LTS }}$ ) results in the behaviour for $M_{B}$ as shown by the full arrows of Figure 4(d).

### 4.4. Avoidance of deadlocks

The solution equations discussed above do not consider the possibility of deadlocks since their derivation is based on trace semantics where the meaning of the specification of a component is the set of possible execution histories or execution sequences. In the context of submodule construction, it is common practice to avoid deadlocks by pruning those transitions in the obtained solution behaviour for $M_{B}$ that may lead to a deadlock. There are two steps in this pruning process:

- If the obtained specification of $\mathrm{M}_{\mathrm{B}}$ (considered alone) contains a deadlock state (such as the state $\{<1 \times 2>,<1 \times 3>\}$ in Figure $4(d)$ ) then all transitions leading to this state should be pruned. This may in turn introduce other deadlock states for which the same kind of pruning should be performed, etc. (In the example of Figure 4(d), the transition labelled $\mathrm{c}_{4}$ should be eliminated).
- Further deadlocks may be detected when the joint behaviour of $M_{A}$ and $M_{B}$ is evaluated (namely $C_{C}{ }^{\text {prod }}$ as defined in Equation (4)). Again, transitions in $M_{B}$ that lead to a joint deadlock state should be pruned. As under Step (1) above, this may be a recursive process. Finally, a joint behaviour without deadlock is obtained; we may call this the "maximal non-blocking behaviour" for $\mathrm{M}_{\mathrm{C}}$, or $\mathrm{C}_{\mathrm{C}}{ }^{\text {non-block }}$. In
certain cases, this behaviour may contain no transition, that is, the system blocks; this means that the given behaviour of $\mathrm{M}_{\mathrm{A}}$ is in some sense incompatible with the required system behaviour $\mathrm{C}_{\mathrm{C}}$.

Fig. 4. (e) behavior (containing a potential deadlock) obtained by the composition of $\mathrm{M}_{\mathrm{A}}$ and the $M_{B}$ obtained in Step 1 above; ( $f$ ) final specification of the behavior of $M_{B}$ (avoiding the deadlock)

In this example, the joint behaviour of $\mathrm{M}_{\mathrm{A}}$ and the behaviour of $\mathrm{M}_{\mathrm{B}}$ after Step (1) above is shown in Figure 4(e). (Note: the states $s_{i}$ are the states shown in Figure 4d: $\mathrm{s}_{1}$ $=\{<1,1>,<2,2>,<3,4>\}, \mathrm{s}_{2}=\{<1,2>\}, \mathrm{s}_{3}=\{<1,4>\}, \mathrm{s}_{4}=\{<1,3>,<4,2>\}$ ). It contains a deadlock state, which may be eliminated by pruning the transition $\mathrm{c}_{4}$ in the behaviour of $\mathrm{M}_{\mathrm{B}}$ and the subsequent state $\mathrm{s}_{4}=\{<1 \times 3>,<4 \times 2>\}$. This leads to the behaviour for $M_{B}$ shown in Figure 4(f). In this example, the whole required behaviour $\mathrm{C}_{\mathrm{C}}$ is realized, that is, $\mathrm{C}_{\mathrm{C}}{ }^{\text {non-block }}=\mathrm{C}_{\mathrm{C}}$.

## 7. Conclusions

The problem of submodule construction (or sometimes called equation solving) has some important applications for real-time control systems, communication gateway design, testing of embedded components, and component re-use for system design in general. Several algorithms for solving this problem have been developed based on different formalisms that are used for defining the dynamic behavior of the desired system and the existing submodule. In this paper, we have shown that this problem can also be formulated in a more general setting using first-order logic. It turns out that solutions to this problem in logic are quite simple. We show in this paper that these solutions (and their proof of correctness) can be mapped into the different specification formalisms considered in the earlier work. Therefore this paper provides, in a sense, new proofs of correctness for the solutions of the submodule construction problem described in earlier work.

The different specification formalisms considered are system components using synchronized rendezvous interactions on several interfaces, or rendezvous with interleaving semantics (e.g. labeled transition systems). Input/output interactions and state machines with queued message passing are considered in a different paper [32]. It is important to note that in the case of regular behaviour specifications in the form
of finite state machines, the solutions to the submodule construction problem can derived by an algorithm which is, in general, of exponential complexity.

We consider in this paper trace semantics, that is, the behaviour of the system, or of a component, is characterized by the set of possible execution histories. This is adequate for safety properties, but ignores issues of liveness, progress, absence of deadlocks and fairness (with the exception of Section 4.4 where deadlock avoidance is discussed). We believe that the issues of hard real-time properties (see for instance [19, 27, 28] ) could also addressed with the approach presented in this paper. However, we are not sure whether it could be helpful for dealing with liveness and progress properties (as for instance discussed in [29, 30, 28, 31]).

It is to be noted that the complexity of the algorithms for deriving the submodule construction solution depends on the specification formalism used. As mentioned above, it is exponential for finite state behavior descriptions, however, it is polynomial if the interactions at the interface $\mathrm{I}_{\mathrm{B}}$ are not hidden; on the other hand, it has been shown to be undecidable for behavior specifications in CSP [5].
