Elementary Probability Theory

Essential Information Theory

1/22/2007

By Barbara Rosario, revised by  
Diana Inkpen

1

## Motivations

---

- Statistical NLP aims to do statistical inference for the field of NL
- *Statistical inference* consists of taking some data (generated in accordance with some unknown *probability distribution*) and then making some inference about this distribution.

1/22/2007

2

## Motivations (Cont)

- An example of statistical inference is the task of *language modeling* (ex how to predict the next word given the previous words)
- In order to do this, we need a *model* of the language.
- Probability theory helps us finding such model

1/22/2007

3

## Probability Theory

- How likely it is that something will happen
- Sample space  $\Omega$  lists of all possible outcomes of an experiment
- The event  $A$  is a subset of  $\Omega$
- Probability function (or distribution)

$$P: \Omega \rightarrow [0,1]$$

1/22/2007

4

## Prior Probability

- *Prior probability*: the probability before we consider any additional knowledge

$$P(A)$$

1/22/2007

5

## Conditional probability

- Sometimes we have partial knowledge about the outcome of an experiment
- Conditional (or Posterior) Probability
- Suppose we know that event B is true
- The probability that A is true given the knowledge about B is expressed by

$$P(A | B)$$

1/22/2007

6

## Conditional probability (cont)

$$\begin{aligned}P(A, B) &= P(A | B)P(B) \\ &= P(B | A)P(A)\end{aligned}$$

- Joint probability of A and B.
- 2-dimensional table with a value in every cell giving the probability of that specific state occurring

1/22/2007

7

## Chain Rule

$$\begin{aligned}P(A, B) &= P(A | B)P(B) \\ &= P(B | A)P(A)\end{aligned}$$

$$P(A, B, C, D) = P(A)P(B | A)P(C | A, B)P(D | A, B, C)$$

1/22/2007

8

## (Conditional) independence

- Two events  $A$  e  $B$  are *independent* of each other if
$$P(A) = P(A|B)$$
- Two events  $A$  and  $B$  are *conditionally independent* of each other given  $C$  if
$$P(A|C) = P(A|B,C)$$

1/22/2007

9

## Bayes' Theorem

- Bayes' Theorem lets us swap the order of dependence between events
- We saw that  $P(A|B) = \frac{P(A,B)}{P(B)}$
- Bayes' Theorem:

$$P(A|B) = \frac{P(B|A)P(A)}{P(B)}$$

1/22/2007

10

## Example

- S:stiff neck, M: meningitis
- $P(S|M) = 0.5$ ,  $P(M) = 1/50,000$   
 $P(S) = 1/20$
- I have stiff neck, should I worry?

$$\begin{aligned} P(M | S) &= \frac{P(S | M)P(M)}{P(S)} \\ &= \frac{0.5 \times 1/50,000}{1/20} = 0.0002 \end{aligned}$$

1/22/2007

11

## Random Variables

- So far, event space that differs with every problem we look at
- Random variables (RV)  $X$  allow us to talk about the probabilities of numerical values that are related to the event space

$$X : \Omega \rightarrow \mathfrak{R}$$

$$X : \Omega \rightarrow \{0,1\}$$

1/22/2007

12

## Expectation

$$p(x) = P(X = x) = P(A_x)$$

$$A_x = \{\omega \in \Omega : X(\omega) = x\}$$

$$\sum_x p(x) = 1 \quad 0 \leq p(x) \leq 1$$

- The Expectation is the *mean or average* of a RV

$$E(x) = \sum_x xp(x) = \mu$$

1/22/2007

13

## Variance

- The *variance* of a RV is a measure of whether the values of the RV tend to be consistent over trials or to vary a lot

$$\begin{aligned} \text{Var}(X) &= \sum_x p(x)(x - E(X))^2 \\ &= E((X - E(X))^2) \\ &= E(X^2) - E^2(X) = \sigma^2 \end{aligned}$$

- $\sigma$  is the *standard deviation*

1/22/2007

14

## Back to the Language Model

- In general, for language events,  $P$  is unknown
- We need to *estimate*  $P$ , (or model  $M$  of the language)
- We'll do this by looking at evidence about what  $P$  must be, based on a sample of data

1/22/2007

15

## Estimation of $P$

- Frequentist statistics
- Bayesian statistics

1/22/2007

16

## Frequentist Statistics

- Relative frequency: proportion of times an outcome  $u$  occurs

$$f_u = \frac{C(u)}{N}$$

- $C(u)$  is the number of times  $u$  occurs in  $N$  trials
- For  $N \rightarrow \infty$  the relative frequency tends to stabilize around some number: probability estimates

1/22/2007

17

## Frequentist Statistics (cont)

- Two different approach:
  - Parametric
  - Non-parametric (distribution free)

1/22/2007

18

## Parametric Methods

- Assume that some phenomenon in language is acceptably modeled by one of the well-known family of distributions (such binomial, normal)
- We have an explicit probabilistic model of the process by which the data was generated, and determining a particular probability distribution within the family requires only the specification of a few parameters (less training data)

1/22/2007

19

## Non-Parametric Methods

- No assumption about the underlying distribution of the data
- For ex, simply estimate  $P$  empirically by counting a large number of random events is a distribution-free method
- Less prior information, more training data needed

1/22/2007

20

## Binomial Distribution (Parametric)

- Series of trials with only two outcomes, each trial being independent from all the others
- Number  $r$  of successes out of  $n$  trials given that the probability of success in any trial is  $p$ :

$$b(r; n, p) = \binom{n}{r} p^r (1-p)^{n-r}$$

1/22/2007

21

## Normal (Gaussian) Distribution (Parametric)

- Continuous
- Two parameters: mean  $\mu$  and standard deviation  $\sigma$

$$n(x; \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

- Used in clustering

1/22/2007

22

## Frequentist Statistics

- D: data
- M: model (distribution P)
- $\Theta$ : parameters (e.g.  $\mu, \sigma$ )
- For M fixed: *Maximum likelihood estimate*: choose  $\theta^*$  such that

$$\theta^* = \underset{\theta}{\operatorname{argmax}} P(D | M, \theta)$$

1/22/2007

23

## Frequentist Statistics

- Model selection, by comparing the maximum likelihood: choose M such that

$$M^* = \underset{M}{\operatorname{argmax}} P(D | M, \theta^*(M))$$

$$\theta^* = \underset{\theta}{\operatorname{argmax}} P(D | M, \theta)$$

1/22/2007

24

## Estimation of P

---

- Frequentist statistics
  - Parametric methods
    - Standard distributions:
      - Binomial distribution (discrete)
      - Normal (*Gaussian*) distribution (continuous)
        - Maximum likelihood
    - Non-parametric methods
  - Bayesian statistics

1/22/2007

25

## Bayesian Statistics

---

- Bayesian statistics measures degrees of belief
- Degrees are calculated by starting with prior beliefs and updating them in face of the evidence, using Bayes theorem

1/22/2007

26

## Bayesian Statistics (cont)

$$\begin{aligned}\hat{M}^* &= \operatorname{argmax}_M P(M | D) \\ &= \operatorname{argmax}_M \frac{P(D | M)P(M)}{P(D)} \\ &= \operatorname{argmax}_M P(D | M)P(M)\end{aligned}$$

MAP is maximum a posteriori distribution

1/22/2007

27

## Bayesian Statistics (cont)

- $M$  is the distribution; for fully describing the model, we need the distribution  $M$  and the parameters  $\theta$

$$\begin{aligned}\hat{M}^* &= \operatorname{argmax}_M P(D | M)P(M) \\ P(D | M) &= \int P(D, \theta | M) d\theta \\ &= \int P(D | M, \theta)P(\theta | M) d\theta\end{aligned}$$

$P(D | M)$  is the marginal likelihood

1/22/2007

28

## Frequentist vs. Bayesian

- Bayesian

$$M^* = \operatorname{argmax}_M P(M) \int P(D | M, \theta) P(\theta | M) d\theta$$

- Frequentist

$$\theta^* = \operatorname{argmax}_\theta P(D | M, \theta) \quad M^* = \operatorname{argmax}_M P(D | M, \theta^*(M))$$

$P(D | M, \theta)$  is the likelihood of data given  $M, \theta$

$P(\theta | M)$  is the parameter prior

$P(M)$  is the model prior

1/22/2007

29

## Bayesian Updating

- How to update  $P(M)$ ?
- We start with a priori probability distribution  $P(M)$ , and when a new datum comes in, we can update our beliefs by calculating the posterior probability  $P(M|D)$ . This then becomes the new prior and the process repeats on each new datum

1/22/2007

30

## Bayesian Decision Theory

- Suppose we have 2 models  $M_1$  and  $M_2$ ; we want to evaluate which model better explains some new data.

$$\frac{P(M_1 | D)}{P(M_2 | D)} = \frac{P(D | M_1)P(M_1)}{P(D | M_2)P(M_2)}$$

$$\text{if } \frac{P(M_1 | D)}{P(M_2 | D)} > 1 \text{ i.e. } P(M_1 | D) > P(M_2 | D)$$

$M_1$  is the most likely model, otherwise  $M_2$

1/22/2007

31

## Essential Information Theory

- Developed by Shannon in the 40s
- Maximizing the amount of information that can be transmitted over an imperfect communication channel
- Data compression (entropy)
- Transmission rate (channel capacity)

1/22/2007

32

## Entropy

- $X$ : discrete RV,  $p(X)$
- Entropy (or self-information)

$$H(p) = H(X) = -\sum_{x \in X} p(x) \log_2 p(x)$$

- Entropy measures the amount of information in a RV; it's the average length of the message needed to transmit an outcome of that variable using the optimal code

1/22/2007

33

## Entropy (cont)

$$H(X) = -\sum_{x \in X} p(x) \log_2 p(x)$$

$$= \sum_{x \in X} p(x) \log_2 \frac{1}{p(x)}$$

$$= E \left( \log_2 \frac{1}{p(X)} \right)$$

$$H(X) \geq 0$$

$$H(X) = 0 \Leftrightarrow p(X) = 1$$

i.e when the value of  $X$  is determinate, hence providing no new information

1/22/2007

34

## Joint Entropy

- The joint entropy of 2 RV  $X, Y$  is the amount of the information needed on average to specify both their values

$$H(X, Y) = - \sum_{x \in X} \sum_{y \in Y} p(x, y) \log p(x, y)$$

1/22/2007

35

## Conditional Entropy

- The conditional entropy of a RV  $Y$  given another RV  $X$ , expresses how much extra information one still needs to supply on average to communicate  $Y$  given that the other party knows  $X$

$$\begin{aligned} H(Y | X) &= \sum_{x \in X} p(x) H(Y | X = x) \\ &= - \sum_{x \in X} p(x) \sum_{y \in Y} p(y | x) \log p(y | x) \\ &= - \sum_{x \in X} \sum_{y \in Y} p(x, y) \log p(y | x) = -E(\log p(Y | X)) \end{aligned}$$

1/22/2007

36

## Chain Rule

$$H(X, Y) = H(X) + H(Y | X)$$

$$H(X_1, \dots, X_n) = H(X_1) + H(X_2 | X_1) + \dots + H(X_n | X_1, \dots, X_{n-1})$$

1/22/2007

37

## Mutual Information

$$H(X, Y) = H(X) + H(Y | X) = H(Y) + H(X | Y)$$

$$H(X) - H(X | Y) = H(Y) - H(Y | X) = I(X; Y)$$

- $I(X; Y)$  is the mutual information between  $X$  and  $Y$ . It is the reduction of uncertainty of one RV due to knowing about the other, or the amount of information one RV contains about the other.

1/22/2007

38

## Mutual Information (cont)

$$I(X; Y) = H(X) - H(X | Y) = H(Y) - H(Y | X)$$

$$I(X; Y) = \sum_{x,y} p(x, y) \log \frac{p(x, y)}{p(x) p(y)}$$

- I is 0 only when X,Y are independent:  
 $H(X|Y)=H(X)$
- $H(X)=H(X)-H(X|X)=I(X;X)$  Entropy is the self-information

1/22/2007

39

## Entropy and Linguistics

- Entropy is measure of uncertainty. The more we know about something the lower the entropy.
- If a language model captures more of the structure of the language, then the entropy should be lower.
- We can use entropy as a measure of the quality of our models

1/22/2007

40

## Entropy and Linguistics (cont)

$$H(p) = H(X) = - \sum_{x \in X} p(x) \log_2 p(x)$$

- H: entropy of language; we don't know  $p(X)$ ; so..?
- Suppose our model of the language is  $q(X)$
- How good estimate of  $p(X)$  is  $q(X)$ ?

1/22/2007

41

## Entropy and Linguistics Kullback-Leibler Divergence

- Relative entropy or KL (Kullback-Leibler) divergence

$$\begin{aligned} D(p||q) &= \sum_{x \in X} p(x) \log \frac{p(x)}{q(x)} \\ &= E_p \left( \log \frac{p(X)}{q(X)} \right) \end{aligned}$$

1/22/2007

42

## Entropy and Linguistics

### KL Divergence (cont)

- Measure of how different two probability distributions are
- Average number of bits that are wasted by encoding events from a distribution  $p$  with a code based on a not-quite right distribution  $q$
- Goal: minimize relative entropy  $D(p||q)$  to have a probabilistic model as accurate as possible

1/22/2007

43

## The Noisy Channel Model

- The aim is to optimize in terms of throughput and accuracy the communication of messages in the presence of noise in the channel
- Duality between compression (achieved by removing all redundancy) and transmission accuracy (achieved by adding controlled redundancy so that the input can be recovered in the presence of noise)

1/22/2007

44

## The Noisy Channel Model (cont)

- Goal: encode the message in such a way that it occupies minimal space while still containing enough redundancy to be able to detect and correct errors

1/22/2007

45

## The Noisy Channel Model (cont)

- Channel capacity: rate at which one can transmit information through the channel with an arbitrary low probability of being unable to recover the input from the output

- $$C = \max_{p(X)} I(X;Y)$$

- We reach a channel capacity if we manage to design an input code X whose distribution  $p(X)$  maximizes I between input and output

1/22/2007

46

## Linguistics and the Noisy Channel Model

- In linguistic we can't control the encoding phase. We want to decode the output to give the most likely input.

$$\hat{I} = \operatorname{argmax}_i p(i|o) = \operatorname{argmax}_i \frac{p(i)p(o|i)}{p(o)} = \operatorname{argmax}_i p(i)p(o|i)$$

1/22/2007

47

## Linguistics and the noisy Channel Model (cont)

$$\hat{I} = \operatorname{argmax}_i p(i|o) = \operatorname{argmax}_i \frac{p(i)p(o|i)}{p(o)} = \operatorname{argmax}_i p(i)p(o|i)$$

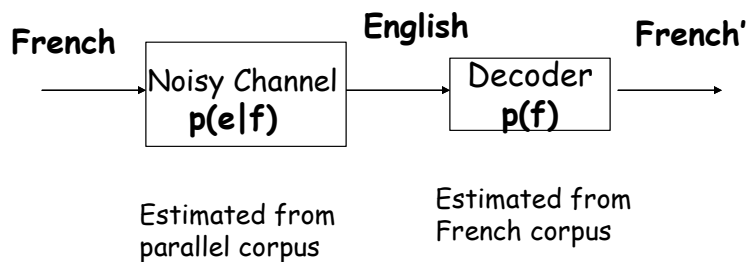

- $p(i)$  is the language model and  $p(o|i)$  is the channel probability
- Ex: Machine translation, optical character recognition, speech recognition

1/22/2007

48

## Machine Translation From English into French

1/22/2007

49

## Noisy channel applications

App.	Input	Output	$p(i)$	$p(o i)$
<b>MT</b>	L2 word sequences	L1 word sequences	L2 language model	Translation model
<b>OCR</b>	actual text	text with mistakes	language model	model of OCR errors
<b>ASR</b>	word sequences	speech signal	language model	acoustic model
<b>POS tagger</b>	POS sequences	word sequences	language model	$p(\text{word} \text{tag})$

1/22/2007
