- Database Interoperability
- Current Issues

Design Problem

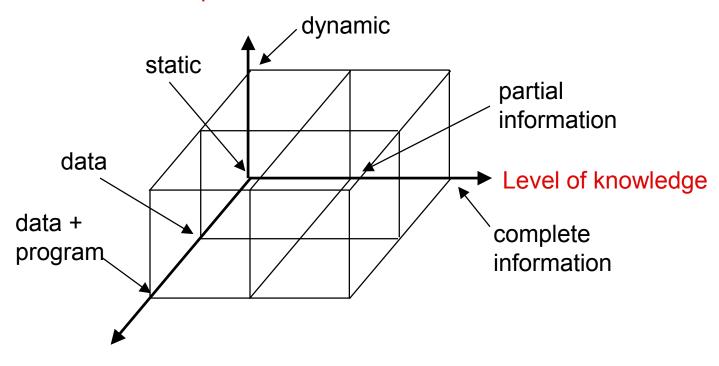

■ In the general setting:

Making decisions about the placement of *data* and *programs* across the sites of a computer network as well as possibly designing the network itself.

- In Distributed DBMS, the placement of applications entails
 - placement of the distributed DBMS software; and
 - placement of the applications that run on the database

Dimensions of the Problem

Access pattern behavior

Level of sharing

Distribution Design

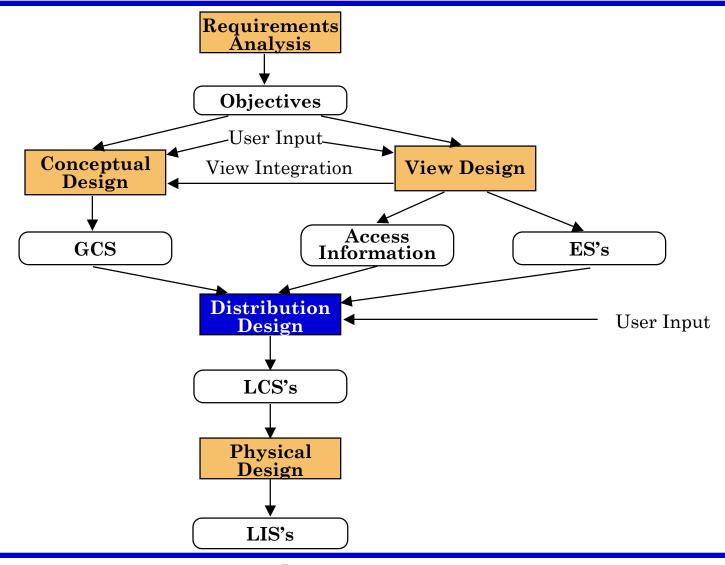

■ Top-down

- mostly in designing systems from scratch
- mostly in homogeneous systems

■ Bottom-up

when the databases already exist at a number of sites

Top-Down Design

Distribution Design Issues

- Why fragment at all?
- 2 How to fragment?
- 6 How much to fragment?
- 4 How to test correctness?
- 6 How to allocate?
- 6 Information requirements?

Fragmentation

- Can't we just distribute relations?
- What is a reasonable unit of distribution?
 - relation
 - views are subsets of relations locality
 - extra communication
 - fragments of relations (sub-relations)
 - concurrent execution of a number of transactions that access different portions of a relation
 - views that cannot be defined on a single fragment will require extra processing
 - semantic data control (especially integrity enforcement) more difficult

Fragmentation Alternatives – Horizontal

PROJ₁: projects with budgets

less than \$200,000

PROJ₂: projects with budgets

greater than or equal to

\$200,000

Degree of Fragmentation

Finding the suitable level of partitioning within this range

Correctness of Fragmentation

Completeness

Decomposition of relation R into fragments $R_1, R_2, ..., R_n$ is complete if and only if each data item in R can also be found in some R_i

Reconstruction

If relation R is decomposed into fragments $R_1, R_2, ..., R_n$, then there should exist some relational operator ∇ such that

$$R = \nabla_{1 \le i \le n} R_i$$

Disjointness

If relation R is decomposed into fragments $R_1, R_2, ..., R_n$, and data item d_i is in R_j , then d_i should not be in any other fragment R_k $(k \neq j)$.

Allocation Alternatives

- Non-replicated
 - partitioned : each fragment resides at only one site
- Replicated
 - fully replicated : each fragment at each site
 - partially replicated: each fragment at some of the sites
- Rule of thumb:

```
If \frac{\text{read - only queries}}{\text{update quries}} \ge 1 replication is advantageous,
```

otherwise replication may cause problems

Comparison of Replication Alternatives

	Full-replication	Partial-replication	Partitioning
QUERY PROCESSING	Easy	✓ Same Di	ifficulty
DIRECTORY MANAGEMENT	Easy or Non-existant	✓ Same Di	ifficulty
CONCURRENCY CONTROL	Moderate Difficult		Easy
RELIABILITY	Very high	High	Low
REALITY	Possible application	Realistic	Possible application

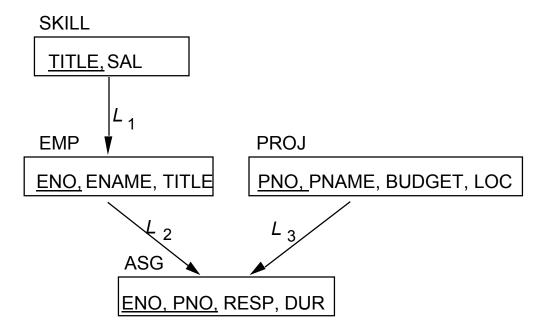

Information Requirements

- Four categories:
 - Database information
 - Application information
 - Communication network information
 - Computer system information

Fragmentation

- Horizontal Fragmentation (HF)
 - Primary Horizontal Fragmentation (PHF)
 - Derived Horizontal Fragmentation (DHF)
- Vertical Fragmentation (VF)
- Hybrid Fragmentation (HF)

- Database Information
 - relationship

ightharpoonup cardinality of each relation: card(R)

- Application Information
 - simple predicates: Given $R[A_1, A_2, ..., A_n]$, a simple predicate p_i is

$$p_i: A_i \Theta \ Value$$

where $\theta \in \{=, <, \leq, >, \geq, \neq\}$, $Value \in D_i$ and D_i is the domain of A_i .

For relation R we define $Pr = \{p_1, p_2, ..., p_m\}$

Example:

PNAME = "Maintenance"

 $BUDGET \leq 200000$

minterm predicates: Given R and $Pr=\{p_1, p_2, ..., p_m\}$ define $M=\{m_1, m_2, ..., m_r\}$ as

$$M=\{\ m_i\ |\ m_i=\ \land_{p_j\in Pr}\ p_j^*\ \},\ 1\leq j\leq m,\ 1\leq i\leq z$$
 where $p_i^*=p_i$ or $p_i^*=\neg(p_i).$

Example

 m_1 : PNAME="Maintenance" \land BUDGET \leq 200000

 m_2 : **NOT**(PNAME="Maintenance") \land BUDGET \leq 200000

 m_3 : PNAME= "Maintenance" \wedge **NOT**(BUDGET \leq 200000)

 m_4 : **NOT**(PNAME="Maintenance") \land **NOT**(BUDGET \leq 200000)

- Application Information
 - \longrightarrow minterm selectivities: $sel(m_i)$
 - The number of tuples of the relation that would be accessed by a user query which is specified according to a given minterm predicate m_i .
 - ightharpoonup access frequencies: $acc(q_i)$
 - ◆ The frequency with which a user application *qi* accesses data.
 - ◆ Access frequency for a minterm predicate can also be defined.

Primary Horizontal Fragmentation

Definition:

$$R_j = \sigma_{F_j}(R), \quad 1 \le j \le w$$

where F_j is a selection formula, which is (preferably) a minterm predicate.

Therefore,

A horizontal fragment R_i of relation R consists of all the tuples of R which satisfy a minterm predicate m_i .

Given a set of minterm predicates M, there are as many horizontal fragments of relation R as there are minterm predicates.

Set of horizontal fragments also referred to as *minterm fragments*.

PHF – Algorithm

Given: A relation R, the set of simple predicates Pr

Output: The set of fragments of $R = \{R_1, R_2, ..., R_w\}$

which obey the fragmentation rules.

Preliminaries:

- ightharpoonup Pr should be *complete*
- ightharpoonup Pr should be minimal

Completeness of Simple Predicates

A set of simple predicates Pr is said to be *complete* if and only if the accesses to the tuples of the minterm fragments defined on Pr requires that two tuples of the same minterm fragment have the same probability of being accessed by any application.

Example:

- Assume PROJ[PNO,PNAME,BUDGET,LOC] has two applications defined on it.
- Find the budgets of projects at each location. (1)
- Find projects with budgets less than \$200000. (2)

Completeness of Simple Predicates

```
According to (1),  Pr = \{ \text{LOC} = \text{``Montreal''}, \text{LOC} = \text{``New York''}, \text{LOC} = \text{``Paris''} \}  which is not complete with respect to (2).  Modify \\ Pr = \{ \text{LOC} = \text{``Montreal''}, \text{LOC} = \text{``New York''}, \text{LOC} = \text{``Paris''}, \\ \text{BUDGET} \leq 2000000, \text{BUDGET} > 2000000 \}  which is complete.
```

Minimality of Simple Predicates

- If a predicate influences how fragmentation is performed, (i.e., causes a fragment f to be further fragmented into, say, f_i and f_j) then there should be at least one application that accesses f_i and f_j differently.
- In other words, the simple predicate should be *relevant* in determining a fragmentation.
- If all the predicates of a set Pr are relevant, then Pr is minimal.

$$rac{acc(m_i)}{card(f_i)}
eq rac{acc(m_j)}{card(f_j)}$$

Minimality of Simple Predicates

Example:

```
Pr ={LOC="Montreal",LOC="New York", LOC="Paris",
BUDGET≤200000,BUDGET>200000}
```

is minimal (in addition to being complete). However, if we add

PNAME = "Instrumentation"

then Pr is not minimal.

COM_MIN Algorithm

Given: a relation R and a set of simple

predicates Pr

Output: a *complete* and *minimal* set of simple

predicates Pr' for Pr

Rule 1: a relation or fragment is partitioned into at least two parts which are accessed differently by at least one application.

COM_MIN Algorithm

• Initialization:

- find a $p_i \in Pr$ such that p_i partitions R according to $Rule\ 1$
- set $Pr' = p_i$; $Pr \leftarrow Pr p_i$; $F \leftarrow f_i$
- 2 Iteratively add predicates to Pr' until it is complete
 - find a $p_j \in Pr$ such that p_j partitions some f_k defined according to minterm predicate over Pr' according to $Rule\ 1$
 - set $Pr' = Pr' \cup p_i$; $Pr \leftarrow Pr p_i$; $F \leftarrow F \cup f_i$
 - if $\exists p_k \in Pr'$ which is nonrelevant then

$$\begin{array}{l} Pr' \leftarrow Pr' - p_k \\ F \leftarrow F - f_k \end{array}$$

Page 5. 27

PHORIZONTAL Algorithm

Makes use of COM_MIN to perform fragmentation.

Input: a relation R and a set of simple

predicates Pr

Output: a set of minterm predicates M according

to which relation R is to be fragmented

- \bullet determine the set I of implications among $p_i \in Pr$
- $oldsymbol{\Phi}$ eliminate the contradictory minterms from M

PHF - Example

- Two candidate relations : PAY and PROJ.
- Fragmentation of relation PAY
 - Application: Check the salary info and determine raise.
 - Employee records kept at two sites application run at two sites
 - Simple predicates

 $p_1: SAL \le 30000$

 $p_2: SAL > 30000$

 $Pr = \{p_1, p_2\}$ which is complete and minimal Pr'=Pr

Minterm predicates

 m_1 : (SAL \leq 30000)

 m_2 : **NOT**(SAL ≤ 30000) = (SAL > 30000)

PHF – Example

PAY₁

TITLE	SAL
Mech. Eng.	27000
Programmer	24000

PAY₂

TITLE	SAL
Elect. Eng.	40000
Syst. Anal.	34000

PHF - Example

■ Fragmentation of relation PROJ

- Applications:
 - Find the name and budget of projects given their no.
 - ✓ Issued at three sites
 - ◆ Access project information according to budget
 - ✓ one site accesses ≤200000 other accesses >200000
- Simple predicates
- **→** For application (1)

 p_1 : LOC = "Montreal"

 p_2 : LOC = "New York"

 p_3 : LOC = "Paris"

For application (2)

 p_4 : BUDGET ≤ 200000

 p_5 : BUDGET > 200000

 $Pr = Pr' = \{p_1, p_2, p_3, p_4, p_5\}$

PHF – Example

■ Fragmentation of relation PROJ continued

Minterm fragments left after elimination

```
\begin{split} m_1: & (\text{LOC} = \text{``Montreal''}) \land (\text{BUDGET} \leq 200000) \\ m_2: & (\text{LOC} = \text{``Montreal''}) \land (\text{BUDGET} > 200000) \\ m_3: & (\text{LOC} = \text{``New York''}) \land (\text{BUDGET} \leq 200000) \\ m_4: & (\text{LOC} = \text{``New York''}) \land (\text{BUDGET} > 200000) \\ m_5: & (\text{LOC} = \text{``Paris''}) \land (\text{BUDGET} \leq 200000) \\ \end{split}
```

PHF – Example

PROJ₁

PNO	PNAME	BUDGET	LOC
P1	Instrumentation	150000	Montreal

PNO	PNAME	BUDGET	LOC
P2	Database Develop.	135000	New York

 $PROJ_4$

PNO	PNAME	BUDGET	LOC
P3	CAD/CAM	250000	New York

 $PROJ_6$

PNO	PNAME	BUDGET	LOC
P4	Maintenance	310000	Paris

PHF - Correctness

Completeness

Since Pr' is complete and minimal, the selection predicates are complete

■ Reconstruction

If relation R is fragmented into $F_R = \{R_1, R_2, ..., R_r\}$

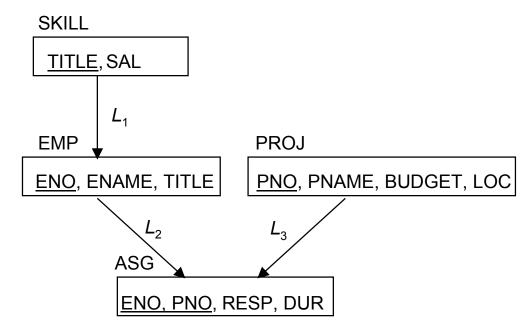

$$R = \bigcup_{\forall R_i \in FR} R_i$$

Disjointness

Minterm predicates that form the basis of fragmentation should be mutually exclusive.

Derived Horizontal Fragmentation

- Defined on a member relation of a link according to a selection operation specified on its owner.
 - Each link is an equijoin.
 - Equijoin can be implemented by means of semijoins.

DHF – **Definition**

Given a link L where owner(L)=S and member(L)=R, the derived horizontal fragments of R are defined as

$$R_i = R \bullet F S_i, 1 \le i \le w$$

where w is the maximum number of fragments that will be defined on R and

$$S_i = \sigma_{F_i}(S)$$

where F_i is the formula according to which the primary horizontal fragment S_i is defined.

DHF – Example

Given link L_1 where owner(L_1)=SKILL and member(L_1)=EMP

 $EMP_1 = EMP \bullet SKILL_1$

 $EMP_2 = EMP \bullet SKILL_2$

where

 $SKILL_1 = \sigma_{SAL \leq 30000} (SKILL)$

 $SKILL_2 = \sigma_{SAL>30000} (SKILL)$

EMP₁

ENO	ENAME	TITLE
E3	A. Lee	Mech. Eng.
E4	J. Miller	Programmer
E7	R. Davis	Mech. Eng.

 EMP_2

ENO	ENAME	TITLE
E1	J. Doe	Elect. Eng.
E2	M. Smith	Syst. Anal.
E5	B. Casey	Syst. Anal.
E6	L. Chu	Elect. Eng.
E8	J. Jones	Syst. Anal.

DHF - Correctness

Completeness

- Referential integrity
- Let R be the member relation of a link whose owner is relation S which is fragmented as $F_S = \{S_1, S_2, ..., S_n\}$. Furthermore, let A be the join attribute between R and S. Then, for each tuple t of R, there should be a tuple t' of S such that

$$t[A]=t'[A]$$

■ Reconstruction

Same as primary horizontal fragmentation.

Disjointness

Simple join graphs between the owner and the member fragments.

Vertical Fragmentation

- Has been studied within the centralized context
 - design methodology
 - physical clustering
- More difficult than horizontal, because more alternatives exist.

Two approaches:

- grouping
 - attributes to fragments
- splitting
 - relation to fragments

Vertical Fragmentation

- Overlapping fragments
 - grouping
- Non-overlapping fragments
 - splitting

We do not consider the replicated key attributes to be overlapping.

Advantage:

Easier to enforce functional dependencies (for integrity checking etc.)

VF - Information Requirements

Application Information

- Attribute affinities
 - a measure that indicates how closely related the attributes are
 - ◆ This is obtained from more primitive usage data
- Attribute usage values
 - Given a set of queries $Q = \{q_1, q_2, ..., q_q\}$ that will run on the relation $R[A_1, A_2, ..., A_n]$,

$$use(q_i, A_j) = \begin{cases} 1 \text{ if attribute } A_j \text{ is referenced by query } q_i \\ 0 \text{ otherwise} \end{cases}$$

 $use(q_i, \bullet)$ can be defined accordingly

VF – Definition of $use(q_i,A_i)$

Consider the following 4 queries for relation PROJ

 q_1 : **SELECT** BUDGET q_2 : **SELECT** PNAME, BUDGET

FROM PROJ FROM PROJ

WHERE PNO=Value

 q_3 : SELECT PNAME q_4 : SELECT SUM(BUDGET)

FROM PROJ **FROM** PROJ

WHERE LOC=Value WHERE LOC=Value

Let A_1 = PNO, A_2 = PNAME, A_3 = BUDGET, A_4 = LOC

VF – Affinity Measure $aff(A_i,A_i)$

The attribute affinity measure between two attributes A_i and A_j of a relation $R[A_1, A_2, ..., A_n]$ with respect to the set of applications $Q = (q_1, q_2, ..., q_q)$ is defined as follows:

$$aff(A_i, A_j) = all queries that access A_i and A_j$$
 (query access)

query access =
$$\frac{\text{access frequency of a query } *}{\text{all sites}}$$

VF - Calculation of $aff(A_i, A_j)$

Assume each query in the previous example accesses the attributes once during each execution.

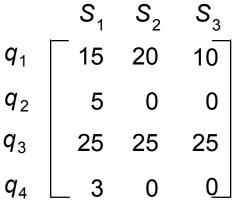

Also assume the access frequencies

Then

$$aff(A_1, A_3) = 15*1 + 20*1+10*1$$

= 45

and the attribute affinity matrix AA is

VF - Clustering Algorithm

- Take the attribute affinity matrix *AA* and reorganize the attribute orders to form clusters where the attributes in each cluster demonstrate high affinity to one another.
- Bond Energy Algorithm (BEA) has been used for clustering of entities. BEA finds an ordering of entities (in our case attributes) such that the global affinity measure

```
AM =  (affinity of A_i and A_j with their neighbors)
```

is maximized.

Bond Energy Algorithm

Input: The AA matrix

Output: The clustered affinity matrix CA which

is a perturbation of AA

- Initialization: Place and fix one of the columns of AA in CA.
- **2** *Iteration*: Place the remaining *n-i* columns in the remaining *i*+1 positions in the *CA* matrix. For each column, choose the placement that makes the most contribution to the global affinity measure.
- **8** Row order: Order the rows according to the column ordering.

Bond Energy Algorithm

"Best" placement? Define contribution of a placement:

$$cont(A_i, A_k, A_j) = 2bond(A_i, A_k) + 2bond(A_k, A_l) - 2bond(A_i, A_j)$$

where

$$bond(A_x,A_y) = \inf_{z=1}^{n} aff(A_z,A_x)aff(A_z,A_y)$$

BEA - Example

Consider the following AA matrix and the corresponding CA matrix where A_1 and A_2 have been placed. Place A_3 :

$$A_{1} \quad A_{2} \quad A_{3} \quad A_{4} \qquad A_{1} \quad A_{2}$$

$$A_{1} \quad A_{2} \quad A_{3} \quad A_{4} \qquad A_{1} \quad A_{2}$$

$$A_{2} \quad A_{3} \quad A_{4} \quad A_{5} \quad A_{5$$

$$\begin{array}{ll} cont(A_0,\!A_3,\!A_1) &= 2bond(A_0\;,A_3) + 2bond(A_3\;,A_1) - 2bond(A_0\;,A_1) \\ &= 2 *\; 0 + 2 *\; 4410 - 2 *0 = 8820 \end{array}$$

Ordering (1-3-2):

$$cont(A_1,A_3,A_2) = 2bond(A_1,A_3) + 2bond(A_3,A_2) - 2bond(A_1,A_2)$$

= 2* 4410 + 2* 890 - 2*225 = 10150

Ordering (2-3-4):

$$cont(A_2, A_3, A_4) = 1780$$

BEA – Example

Therefore, the CA matrix has to form

$$A_1$$
 A_3 A_2

$$\begin{bmatrix} 45 & 45 & 0 \\ 0 & 5 & 80 \\ 45 & 53 & 5 \\ 0 & 3 & 75 \end{bmatrix}$$

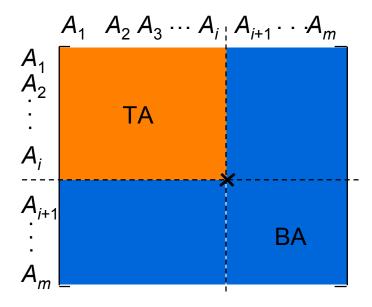

BEA – Example

When A_4 is placed, the final form of the CA matrix (after row organization) is

$$A_1$$
 A_3 A_2 A_4 A_5 A_6 A_7 A_8 A_8

VF - Algorithm

How can you divide a set of clustered attributes $\{A_1, A_2, ..., A_n\}$ into two (or more) sets $\{A_1, A_2, ..., A_i\}$ and $\{A_i, ..., A_n\}$ such that there are no (or minimal) applications that access both (or more than one) of the sets.

VF - ALgorithm

Define

TQ =set of applications that access only TA

BQ = set of applications that access only BA

OQ = set of applications that access both TA and BA

and

CTQ = total number of accesses to attributes by applications that access only TA

CBQ = total number of accesses to attributes by applications that access only BA

COQ = total number of accesses to attributes by applications that access both TA and BA

Then find the point along the diagonal that maximizes

 $CTQ*CBQ-COQ^2$

VF – Algorithm

Two problems:

- Cluster forming in the middle of the *CA* matrix
 - Shift a row up and a column left and apply the algorithm to find the "best" partitioning point
 - Do this for all possible shifts
 - $ightharpoonup Cost O(m^2)$
- 2 More than two clusters
 - ightharpoonup m-way partitioning
 - try 1, 2, ..., *m*-1 split points along diagonal and try to find the best point for each of these
 - $ightharpoonup Cost O(2^m)$

VF - Correctness

A relation R, defined over attribute set A and key K, generates the vertical partitioning $F_R = \{R_1, R_2, ..., R_r\}$.

- Completeness
 - The following should be true for *A*:

$$A = \bigcup A_{R_i}$$

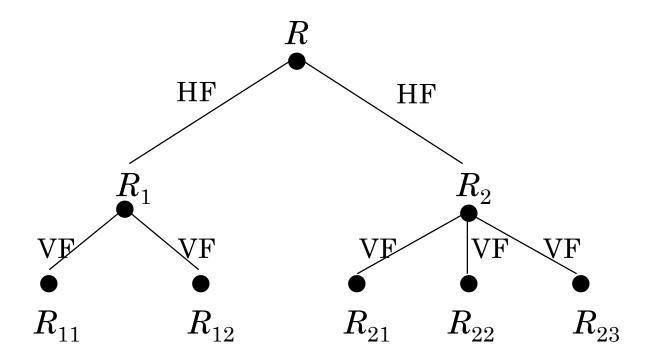

- Reconstruction
 - Reconstruction can be achieved by

$$R = \mathbb{O}_K$$

$$R_i \, \forall R_i \in F_R$$

- Disjointness
 - TID's are not considered to be overlapping since they are maintained by the system
 - Duplicated keys are not considered to be overlapping

Hybrid Fragmentation

Fragment Allocation

■ Problem Statement

Given

$$F = \{F_1, F_2, ..., F_n\}$$
 fragments
 $S = \{S_1, S_2, ..., S_m\}$ network sites
 $Q = \{q_1, q_2, ..., q_q\}$ applications

Find the "optimal" distribution of F to S.

- Optimality
 - Minimal cost
 - Communication + storage + processing (read & update)
 - Cost in terms of time (usually)
 - Performance

Response time and/or throughput

- Constraints
 - Per site constraints (storage & processing)

Information Requirements

- Database information
 - selectivity of fragments
 - size of a fragment
- Application information
 - access types and numbers
 - access localities
- Communication network information
 - unit cost of storing data at a site
 - unit cost of processing at a site
- Computer system information
 - bandwidth
 - latency
 - communication overhead

Allocation

File Allocation (FAP) vs Database Allocation (DAP):

- Fragments are not individual files
 - relationships have to be maintained
- Access to databases is more complicated
 - remote file access model not applicable
 - relationship between allocation and query processing
- Cost of integrity enforcement should be considered
- Cost of concurrency control should be considered

Allocation – Information Requirements

- Database Information
 - selectivity of fragments
 - size of a fragment
- Application Information
 - number of read accesses of a query to a fragment
 - number of update accesses of query to a fragment
 - A matrix indicating which queries updates which fragments
 - A similar matrix for retrievals
 - originating site of each query
- Site Information
 - unit cost of storing data at a site
 - unit cost of processing at a site
- Network Information
 - communication cost/frame between two sites
 - frame size

General Form

min(Total Cost)

subject to

response time constraint

storage constraint

processing constraint

Decision Variable

$$x_{ij} = \begin{cases} 1 \text{ if fragment } F_i \text{ is stored at site } S_j \\ 0 \text{ otherwise} \end{cases}$$

■ Total Cost

query processing cost +
all queries

cost of storing a fragment at a site
all sites all fragments

- Storage Cost (of fragment F_j at S_k)
 - (unit storage cost at S_k) * (size of F_j) * x_{jk}
- Query Processing Cost (for one query)

processing component + transmission component

Query Processing Cost

Processing component

access cost + integrity enforcement cost + concurrency control cost

Access cost

```
all sites all fragments (no. of update accesses+ no. of read accesses) * x_{ij} *local processing cost at a site
```

- Integrity enforcement and concurrency control costs
 - ◆ Can be similarly calculated

Query Processing Cost

Transmission component

cost of processing updates + cost of processing retrievals

Cost of updates

all sites update message cost + all sites

all sites all fragments acknowledgment cost

Retrieval Cost

 $\min_{all \ sites} (cost \ of \ retrieval \ command \ +$

cost of sending back the result)

Constraints

Response Time

execution time of query \leq max. allowable response time for that query

Storage Constraint (for a site)

storage requirement of a fragment at that site \leq all fragments

storage capacity at that site

Processing constraint (for a site)

 $_{
m all~queries}$ processing load of a query at that site \leq

processing capacity of that site

- Solution Methods
 - → FAP is NP-complete
 - DAP also NP-complete
- Heuristics based on
 - single commodity warehouse location (for FAP)
 - knapsack problem
 - branch and bound techniques
 - network flow

- Attempts to reduce the solution space
 - assume all candidate partitionings known; select the "best" partitioning
 - ignore replication at first
 - sliding window on fragments
