- Background
- Distributed DBMS Architecture
- Distributed Database Design
- Semantic Data Control
- Distributed Query Processing
 - Query Processing Methodology
 - Distributed Query Optimization
- Distributed Transaction Management
- Parallel Database Systems
- Distributed Object DBMS
- Database Interoperability
- **Current Issues**

Query Processing

Query Processing Components

- Query language that is used
 - ➡ SQL: "intergalactic dataspeak"
- Query execution methodology
 - The steps that one goes through in executing highlevel (declarative) user queries.
- Query optimization
 - How do we determine the "best" execution plan?

Selecting Alternatives

SELECT	ENAME
FROM	EMP,ASG
WHERE	EMP.ENO = ASG.ENO
AND	DUR > 37

Strategy 1

 $\Pi_{ENAME}(\sigma_{DUR>37 \wedge EMP.ENO=ASG.ENO} \, (EMP \times ASG))$ Strategy 2

 $\Pi_{\text{ENAME}}(\text{EMP}\bowtie_{\text{ENO}}(\sigma_{\text{DUR>37}}(\text{ASG})))$

Strategy 2 avoids Cartesian product, so is "better"

What is the Problem?

Cost of Alternatives

Assume:

- \implies size(EMP) = 400, size(ASG) = 1000
- tuple access cost = 1 unit; tuple transfer cost = 10 units

Strategy 1

produce ASG': (10+10)*tuple access cost	20
transfer ASG' to the sites of EMP: (10+10)*tuple transfer cost	t 200
produce EMP': (10+10) *tuple access cost*2	40
transfer EMP' to result site: (10+10) *tuple transfer cost	200
Total cost	460
rategy 2	
transfer EMP to site 5:400*tuple transfer cost	4,000
transfer ASG to site 5 :1000*tuple transfer cost	10,000
produce ASG':1000*tuple access cost	1,000
join EMP and ASG':400*20*tuple access cost	8,000
Total cost	23,000
	produce ASG': (10+10)*tuple access cost transfer ASG' to the sites of EMP: (10+10)*tuple transfer cost produce EMP': (10+10) *tuple access cost*2 transfer EMP' to result site: (10+10) *tuple transfer cost Total cost rategy 2 transfer EMP to site 5:400*tuple transfer cost transfer ASG to site 5 :1000*tuple transfer cost produce ASG':1000*tuple access cost join EMP and ASG':400*20*tuple access cost Total cost

Query Optimization Objectives

Minimize a cost function

I/O cost + CPU cost + communication cost

These might have different weights in different distributed environments

Wide area networks

- communication cost will dominate
 - low bandwidth
 - low speed
 - high protocol overhead
- most algorithms ignore all other cost components

Local area networks

- communication cost not that dominant
- total cost function should be considered

Can also maximize throughput

Complexity of Relational Operations

Assume

- \blacksquare relations of cardinality n
- 🔹 sequential scan

Operation	Complexity
Select Project (without duplicate elimination)	O(<i>n</i>)
Project (with duplicate elimination) Group	$O(n \log n)$
Join Semi-join Division Set Operators	$O(n \log n)$
Cartesian Product	$O(n^2)$

Query Optimization Issues – Types of Optimizers

- Exhaustive search
 - cost-based
 - optimal
 - combinatorial complexity in the number of relations
- Heuristics
 - not optimal
 - regroup common sub-expressions
 - perform selection, projection first
 - replace a join by a series of semijoins
 - reorder operations to reduce intermediate relation size
 - optimize individual operations

Query Optimization Issues – Optimization Granularity

Single query at a time

cannot use common intermediate results

Multiple queries at a time

- efficient if many similar queries
- decision space is much larger

Query Optimization Issues – Optimization Timing

Static

- compilation optimize prior to the execution
- difficult to estimate the size of the intermediate results error propagation
- can amortize over many executions
- ₩ R*
- Dynamic
 - run time optimization
 - exact information on the intermediate relation sizes
 - have to reoptimize for multiple executions
 - Distributed INGRES
- Hybrid
 - compile using a static algorithm
 - if the error in estimate sizes > threshold, reoptimize at run time
 - MERMAID

Query Optimization Issues – Statistics

Relation

- cardinality
- ➡ size of a tuple
- fraction of tuples participating in a join with another relation
- Attribute
 - cardinality of domain
 - actual number of distinct values
- Common assumptions
 - independence between different attribute values
 - uniform distribution of attribute values within their domain

Query Optimization Issues – Decision Sites

Centralized

- single site determines the "best" schedule
- simple
- need knowledge about the entire distributed database
- Distributed
 - cooperation among sites to determine the schedule
 - need only local information
 - cost of cooperation
- Hybrid
 - one site determines the global schedule
 - each site optimizes the local subqueries

Query Optimization Issues – Network Topology

■ Wide area networks (WAN) – point-to-point

- characteristics
 - low bandwidth
 - low speed
 - high protocol overhead
- communication cost will dominate; ignore all other cost factors
- global schedule to minimize communication cost
- local schedules according to centralized query optimization
- Local area networks (LAN)
 - communication cost not that dominant
 - total cost function should be considered
 - broadcasting can be exploited (joins)
 - special algorithms exist for star networks

Distributed Query Processing Methodology

Step 1 – Query Decomposition

Input : Calculus query on global relations

- Normalization
 - manipulate query quantifiers and qualification
- Analysis
 - detect and reject "incorrect" queries
 - possible for only a subset of relational calculus

Simplification

- eliminate redundant predicates
- Restructuring
 - calculus query algebraic query
 - more than one translation is possible
 - **use transformation rules**

Normalization

Lexical and syntactic analysis

- check validity (similar to compilers)
- check for attributes and relations
- type checking on the qualification
- Put into normal form
 - Conjunctive normal form

 $(p_{11} \lor p_{12} \lor \ldots \lor p_{1n}) \land \ldots \land (p_{m1} \lor p_{m2} \lor \ldots \lor p_{mn})$

Disjunctive normal form

 $(p_{11} \land p_{12} \land \ldots \land p_{1n}) \lor \ldots \lor (p_{m1} \land p_{m2} \land \ldots \land p_{mn})$

- OR's mapped into union
- AND's mapped into join or selection

Analysis

- Refute incorrect queries
- Type incorrect
 - If any of its attribute or relation names are not defined in the global schema
 - If operations are applied to attributes of the wrong type
- Semantically incorrect
 - Components do not contribute in any way to the generation of the result
 - Only a subset of relational calculus queries can be tested for correctness
 - Those that do not contain disjunction and negation
 - ➡ To detect
 - connection graph (query graph)
 - ♦ join graph

Analysis – Example

SELECT	ENAME, RESP
FROM	EMP, ASG, PROJ
WHERE	EMP.ENO = ASG.ENO
AND	ASG.PNO = PROJ.PNO
AND	PNAME = "CAD/CAM"
AND	DUR \geq 36
AND	TITLE = "Programmer"

If the query graph is not connected, the query is wrong.

SELECT	ENAME, RESP
FROM	EMP, ASG, PROJ
WHERE	EMP.ENO = ASG.ENO
AND	PNAME = "CAD/CAM"
AND	DUR \geq 36
AND	TITLE = "Programmer"

Simplification

- Why simplify?
 - Remember the example
- How? Use transformation rules
 - elimination of redundancy
 - idempotency rules

 $\begin{array}{l} p_1 \wedge \neg (p_1) \Leftrightarrow \text{false} \\ p_1 \wedge (p_1 \vee p_2) \Leftrightarrow p_1 \\ p_1 \vee \text{false} \Leftrightarrow p_1 \end{array}$

•••

- application of transitivity
- use of integrity rules

Simplification – Example

SELECT	TITLE
FROM	EMP
WHERE	EMP.ENAME = "J. Doe"
OR	(NOT (EMP.TITLE = "Programmer")
AND	(EMP.TITLE = "Programmer"
OR	<pre>EMP.TITLE = "Elect. Eng.")</pre>
AND	NOT (EMP.TITLE = "Elect. Eng."))

SELECT	TITLE	
FROM	EMP	
WHERE	EMP.ENAME = "J. Doe"	

Restructuring

Restructuring – Transformation Rules

- Commutativity of binary operations
 - $\implies R \times S \Leftrightarrow S \times R$
 - $\blacksquare R \bowtie S \Leftrightarrow S \bowtie R$
 - $\implies R \cup S \Leftrightarrow S \cup R$
- Associativity of binary operations
 - $(R \times S) \times T \Leftrightarrow R \times (S \times T)$
 - $\blacksquare (R \bowtie S) \bowtie T \Leftrightarrow R \bowtie (S \bowtie T)$
- Idempotence of unary operations
 - $\implies \Pi_{A'}(\Pi_{A'}(\mathbf{R})) \Leftrightarrow \Pi_{A'}(\mathbf{R})$
 - $\overset{\bullet}{\longrightarrow} \sigma_{p_1(A_1)}(\sigma_{p_2(A_2)}(R)) = \sigma_{p_1(A_1) \land p_2(A_2)}(R)$ where *R*[*A*] and *A'* \subseteq *A*, *A''* \subseteq *A* and *A'* \subseteq *A''*
- Commuting selection with projection

Restructuring – Transformation Rules

- Commuting selection with binary operations
 - $\implies \sigma_{p(A)}(R \times S) \Leftrightarrow (\sigma_{p(A)}(R)) \times S$
 - $\implies \sigma_{p(A_i)}(R \bowtie_{(A_j, B_k)} S) \Leftrightarrow (\sigma_{p(A_i)}(R)) \bowtie_{(A_j, B_k)} S$
 - $\bullet \sigma_{p(A_i)}(R \cup T) \Leftrightarrow \sigma_{p(A_i)}(R) \cup \sigma_{p(A_i)}(T)$

where A_i belongs to R and T

- Commuting projection with binary operations
 - $\blacksquare \Pi_{C}(R \times S) \Leftrightarrow \Pi_{A'}(R) \times \Pi_{B'}(S)$
 - $\blacksquare \ \Pi_{C}(R \bowtie_{(A_{j},B_{k})} S) \Leftrightarrow \Pi_{A'}(R) \bowtie_{(A_{j},B_{k})} \Pi_{B'}(S)$
 - $\blacksquare \Pi_{C}(R \cup S) \Leftrightarrow \Pi_{C}(R) \cup \Pi_{C}(S)$

where R[A] and S[B]; $C = A' \cup B'$ where $A' \subseteq A, B' \subseteq B$

Example

Restructuring

Step 2 – Data Localization

Input: Algebraic query on distributed relations

- Determine which fragments are involved
- Localization program
 - substitute for each global query its materialization program
 - optimize

Example

Provides Parallellism

Eliminates Unnecessary Work

- Reduction with selection
 - Relation *R* and $F_R = \{R_1, R_2, ..., R_w\}$ where $R_j = \sigma_{p_j}(R)$ $\sigma_{p_i}(R_j) = \phi$ if $\forall x$ in $R: \neg (p_i(x) \land p_j(x))$

Example

SELECT	*
FROM	EMP
WHERE	ENO="E5"

- Reduction with join
 - Possible if fragmentation is done on join attribute
 - Distribute join over union

 $(R_1 \cup R_2) \bowtie S \Leftrightarrow (R_1 \bowtie S) \cup (R_2 \bowtie S)$

• Given
$$R_i = \sigma_{p_i}(R)$$
 and $R_j = \sigma_{p_j}(R)$

 $R_i \bowtie R_j = \phi \text{ if } \forall x \text{ in } R_i, \forall y \text{ in } R_j: \neg (p_i(x) \land p_j(y))$

- Distribute join over unions
- Apply the reduction rule

Reduction for VF

Find useless (not empty) intermediate relations

Relation *R* defined over attributes $A = \{A_1, ..., A_n\}$ vertically fragmented as $R_i = \prod_{A'} (R)$ where $A' \subseteq A$:

 $\Pi_{D,K}(R_i) \text{ is useless if the set of projection attributes } D \text{ is not in } A'$ Example: $\text{EMP}_1 = \Pi_{\text{ENO,ENAME}} \text{ (EMP)}; \text{ EMP}_2 = \Pi_{\text{ENO,TITLE}} \text{ (EMP)}$ SELECT ENAME

FROM EMP

Reduction for DHF

- Rule :
 - Distribute joins over unions
 - Apply the join reduction for horizontal fragmentation
- Example

ASG₁: ASG $\bowtie_{ENO} EMP_1$ ASG₂: ASG $\bowtie_{ENO} EMP_2$ EMP₁: $\sigma_{TITLE="Programmer"}$ (EMP) EMP₂: $\sigma_{TITLE="Programmer"}$ (EMP)

Query

SELECT	*
FROM	EMP, ASG
WHERE	ASG.ENO = EMP.ENO
AND	EMP.TITLE = "Mech. Eng."

Reduction for DHF

Reduction for DHF

Reduction for HF

- Combine the rules already specified:
 - Remove empty relations generated by contradicting selections on horizontal fragments;
 - Remove useless relations generated by projections on vertical fragments;
 - Distribute joins over unions in order to isolate and remove useless joins.

Reduction for HF

Example

Step 3 – Global Query Optimization

Input: Fragment query

- Find the *best* (not necessarily optimal) global schedule
 - Minimize a cost function
 - Distributed join processing
 - Bushy vs. linear trees
 - Which relation to ship where?
 - Ship-whole vs ship-as-needed
 - Decide on the use of semijoins
 - Semijoin saves on communication at the expense of more local processing.
 - Join methods
 - nested loop vs ordered joins (merge join or hash join)

Cost-Based Optimization

- Solution space
 - The set of equivalent algebra expressions (query trees).
- Cost function (in terms of time)
 - ➡ I/O cost + CPU cost + communication cost
 - These might have different weights in different distributed environments (LAN vs WAN).
 - Can also maximize throughput
- Search algorithm
 - How do we move inside the solution space?
 - Exhaustive search, heuristic algorithms (iterative improvement, simulated annealing, genetic,...)

Query Optimization Process

Search Space

Search space characterized by PNO_ alternative execution plans \bowtie ENO PROJ Focus on join trees • For N relations, there are O(N!)EMP ASG equivalent join trees that can be obtained by applying ENO commutativity and associativity rules \bowtie EMP PNQ SELECT ENAME, RESP PROJ ASG FROM EMP, ASG, PROJ EMP.ENO=ASG.ENO WHERE ⊨ ENO, PNO AND ASG. PNO=PROJ. PNO ASG

PROJ

EMP

Search Space

- Restrict by means of heuristics
 - Perform unary operations before binary operations
- Restrict the shape of the join tree
 - Consider only linear trees, ignore bushy ones

Search Strategy

- How to "move" in the search space.
- Deterministic
 - Start from base relations and build plans by adding one relation at each step
 - Dynamic programming: breadth-first
 - Greedy: depth-first
- Randomized
 - Search for optimalities around a particular starting point
 - Trade optimization time for execution time
 - \blacksquare Better when > 5-6 relations
 - Simulated annealing
 - Iterative improvement

Search Strategies

Deterministic

Cost Functions

- Total Time (or Total Cost)
 - Reduce each cost (in terms of time) component individually
 - ➡ Do as little of each cost component as possible
 - Optimizes the utilization of the resources

- Response Time
 - Do as many things as possible in parallel
 - May increase total time because of increased total activity

Total Cost

Summation of all cost factors

Total cost = CPU cost + I/O cost + communication cost

CPU cost = unit instruction cost * no.of instructions

I/O cost = unit disk I/O cost * no. of disk I/Os

communication cost = message initiation + transmission

Total Cost Factors

Wide area network

- message initiation and transmission costs high
- local processing cost is low (fast mainframes or minicomputers)
- ratio of communication to I/O costs = 20:1
- Local area networks
 - communication and local processing costs are more or less equal
 - ➡ ratio = 1:1.6

Response Time

Elapsed time between the initiation and the completion of a query

Response time = CPU time + I/O time + communication time

CPU time	= unit instruction time * no. of sequential
	instructions

I/O time = unit I/O time * no. of sequential I/Os

communication time = unit msg initiation time * no. of sequential msg + unit transmission time * no. of sequential bytes

```
Assume that only the communication cost is considered
Total time = 2 * message initialization time + unit
transmission time * (x+y)
```

Response time = max {time to send x from 1 to 3, time to send y from 2 to 3}

```
time to send x from 1 to 3 = message initialization time + unit transmission time * x
```

time to send *y* from 2 to 3 = message initialization time + unit transmission time * *y*

Optimization Statistics

- Primary cost factor: size of intermediate relations
- Make them precise more costly to maintain
 - For each relation $R[A_1, A_2, ..., A_n]$ fragmented as $R_1, ..., R_r$
 - length of each attribute: *length*(*Ai*)
 - the number of distinct values for each attribute in each fragment: $card(\prod_{A_i} R_j)$
 - maximum and minimum values in the domain of each attribute: *min(A_i)*, *max(A_i)*
 - the cardinalities of each domain: $card(dom[A_i])$
 - the cardinalities of each fragment: $card(R_j)$
 - Selectivity factor of each operation for relations
 - For joins

$$SF_{\bowtie}(R,S) = \frac{card(R \bowtie S)}{card(R) * card(S)}$$

Intermediate Relation Sizes

Selection

$$size(R) = card(R) * length(R)$$
$$card(\sigma_F(R)) = SF_{\sigma}(F) * card(R)$$

where

$$S F_{\sigma}(A = value) = \frac{1}{card(\prod_{A}(R))}$$
$$S F_{\sigma}(A > value) = \frac{max(A) - value}{max(A) - min(A)}$$
$$S F_{\sigma}(A < value) = \frac{value - max(A)}{max(A) - min(A)}$$

$$\begin{split} SF_{\sigma}(p(A_{i}) \wedge p(A_{j})) &= SF_{\sigma}(p(A_{i})) * SF_{\sigma}(p(A_{j})) \\ SF_{\sigma}(p(A_{i}) \vee p(A_{j})) &= SF_{\sigma}(p(A_{i})) + SF_{\sigma}(p(A_{j})) - (SF_{\sigma}(p(A_{i})) * SF_{\sigma}(p(A_{j}))) \\ SF_{\sigma}(A \in value) &= SF_{\sigma}(A = value) * card(\{values\}) \end{split}$$

Intermediate Relation Sizes

Projection

 $card(\Pi_A(R))=card(R)$

Cartesian Product

 $card(R \times S) = card(R) * card(S)$

Union

upper bound: $card(R \cup S) = card(R) + card(S)$

lower bound: $card(R \cup S) = max\{card(R), card(S)\}$

Set Difference

upper bound: card(R-S) = card(R)lower bound: 0

Intermediate Relation Size

Join

Special case: A is a key of R and B is a foreign key of S;

 $card(R \bowtie_{A=B} S) = card(S)$

More general:

 $card(R \bowtie S) = SF_{\bowtie}* card(R) * card(S)$

Semijoin

$$card(R \bowtie_A S) = SF_{\bowtie}(S.A) * card(R)$$

where

$$SF_{\bowtie}(R\bowtie_{A} S) = SF_{\bowtie}(S.A) = \frac{card(\prod_{A}(S))}{card(dom[A])}$$

Centralized Query Optimization

■ INGRES

- \mu dynamic
- interpretive
- System R
 - ➡ static
 - exhaustive search

INGRES Algorithm

- Decompose each multi-variable query into a sequence of mono-variable queries with a common variable
- Process each by a one variable query processor
 - Choose an initial execution plan (heuristics)
 - Order the rest by considering intermediate relation sizes

No statistical information is maintained

INGRES Algorithm–Decomposition

Replace an n variable query q by a series of queries

$$q_1 \rightarrow q_2 \rightarrow \ldots \rightarrow q_n$$

where q_i uses the result of q_{i-1} .

- Detachment
 - Query *q* decomposed into $q' \rightarrow q''$ where q' and q'' have a common variable which is the result of q'
- Tuple substitution
 - Replace the value of each tuple with actual values and simplify the query

 $q(V_1, V_2, \dots, V_n) \to (q'(t_1, V_2, V_2, \dots, V_n), t_1 \in R)$

Detachment

- $q': SELECT \qquad V_1 \cdot A_1 \text{ INTO } R_1 \text{ '}$ $FROM \qquad R_1 \quad V_1$ $WHERE \qquad P_1 (V_1 \cdot A_1)$
- $q'': SELECT \qquad V_2 . A_2 , \dots, V_n . A_n$ FROM $R_1 ' V_1 , R_2 V_2 , \dots, R_n V_n$ WHERE $P_2 (V_1 . A_1 , V_2 . A_2 , \dots, V_n . A_n)$

Detachment Example

Names of employees working on CAD/CAM project

q_1 :	SELECT	EMP.ENAME
	FROM	EMP, ASG, PROJ
	WHERE	EMP.ENO=ASG.ENO
	AND	ASG.PNO=PROJ.PNO
	AND	PROJ.PNAME="CAD/CAM"

q₁₁: SELECT PROJ.PNO INTO JVAR
FROM PROJ
WHERE PROJ.PNAME="CAD/CAM"

q':	SELECT	EMP.ENAME
	FROM	EMP,ASG,JVAR
	WHERE	EMP.ENO=ASG.ENO
	AND	ASG.PNO=JVAR.PNO

Detachment Example (cont'd)

- q': SELECT EMP.ENAME
 - **FROM** EMP, ASG, JVAR
 - WHERE EMP.ENO=ASG.ENO
 - AND ASG.PNO=JVAR.PNO

- q_{12} : Select Asg.eno into gvar
 - **FROM** ASG, JVAR
 - WHERE ASG.PNO=JVAR.PNO
- q₁₃: SELECT EMP.ENAME
 FROM EMP,GVAR
 WHERE EMP.ENO=GVAR.ENO

Tuple Substitution

- $\begin{array}{c} q_{11} \text{ is a mono-variable query} \\ q_{12} \text{ and } q_{13} \text{ is subject to tuple substitution} \\ \text{Assume GVAR has two tuples only: <E1> and <E2> \\ \text{Then } q_{13} \text{ becomes} \\ q_{131}\text{: SELECT} & \text{EMP}.\text{ENAME} \\ & \text{FROM} & \text{EMP} \\ & \text{WHERE} & \text{EMP}.\text{ENO="E1"} \\ \end{array}$ $\begin{array}{c} q_{132}\text{: SELECT} & \text{EMP}.\text{ENAME} \\ & \text{FROM} & \text{EMP} \\ & \text{WHERE} & \text{EMP}.\text{ENO="E1"} \\ \end{array}$
 - WHERE EMP.ENO="E2"

System R Algorithm

- Simple (i.e., mono-relation) queries are executed according to the best access path
- e Execute joins
 - **2.1** Determine the possible ordering of joins
 - **2.2** Determine the cost of each ordering
 - **2.3** Choose the join ordering with minimal cost

System R Algorithm

For joins, two alternative algorithms :

Nested loops

for each tuple of *external* relation (cardinality n_1) for each tuple of *internal* relation (cardinality n_2)

join two tuples if the join predicate is true

end

 \boldsymbol{end}

- Complexity: $n_1 * n_2$
- Merge join

 sort relations

merge relations

• Complexity: $n_1 + n_2$ if relations are previously sorted and equijoin

System R Algorithm – Example

Names of employees working on the CAD/CAM project Assume

- ➡ EMP has an index on ENO,
- ➡ ASG has an index on PNO,
- ➡ PROJ has an index on PNO and an index on PNAME

System R Example (cont'd)

1 Choose the best access paths to each relation

- ➡ EMP: sequential scan (no selection on EMP)
- ➡ ASG: sequential scan (no selection on ASG)
- ▶ PROJ: index on PNAME (there is a selection on PROJ based on PNAME)
- Otermine the best join ordering
 - ► EMP ASG PROJ
 - ➡ ASG ▷ PROJ ▷ EMP
 - ► PROJ⋈ASG⋈EMP
 - \blacksquare ASG \bowtie EMP \bowtie PROJ
 - \blacksquare EMP × PROJ \bowtie ASG
 - \blacksquare PROJ × EMP \bowtie ASG
 - Select the best ordering based on the join costs evaluated according to the two methods

System R Algorithm

System R Algorithm

- ((PROJ ⋈ASG) ⋈EMP) has a useful index on the select attribute and direct access to the join attributes of ASG and EMP
- Therefore, chose it with the following access methods:
 - select PROJ using index on PNAME
 - then join with ASG using index on PNO
 - then join with EMP using index on ENO

Join Ordering in Fragment Queries

Ordering joins

- Distributed INGRES
- ➡ System R*
- Semijoin ordering
 - ➡ SDD-1
Join Ordering

Consider two relations only

$$R \xrightarrow{\text{if size } (R) < \text{size } (S)} S$$

$$If size (R) > size (S)$$

- Multiple relations more difficult because too many alternatives.
 - Compute the cost of all alternatives and select the best one.
 - Necessary to compute the size of intermediate relations which is difficult.
 - Use heuristics

Join Ordering – Example

Join Ordering – Example

Execution alternatives:

- 1. EMP \rightarrow Site 2 Site 2 computes EMP'=EMP \bowtie ASG EMP' \rightarrow Site 3 Site 3 computes EMP \bowtie PROJ
- 2. ASG → Site 1
 Site 1 computes EMP'=EMP ASG
 EMP' → Site 3
 Site 3 computes EMP' PROJ
- $3. ASG \rightarrow Site 3$ $4. PROJ \rightarrow Site 2$ Site 3 computes ASG'=ASG $\bowtie PROJ$ Site 2 computes PROJ'=PROJ $\bowtie ASG$ ASG' $\rightarrow Site 1$ $PROJ' \rightarrow Site 1$ Site 1 computes ASG' $\bowtie EMP$ Site 1 computes PROJ' $\bowtie EMP$
- 5. EMP \rightarrow Site 2 PROJ \rightarrow Site 2 Site 2 computes EMP PROJ ASG

Semijoin Algorithms

Consider the join of two relations:

- \blacksquare R[A] (located at site 1)
- \blacksquare S[A] (located at site 2)
- Alternatives:

1 Do the join $R \bowtie_A S$

2 Perform one of the semijoin equivalents

$$\begin{split} R \bowtie_{\!A} S \ \Leftrightarrow \ (R \bowtie_A S) \bowtie_A S \\ \Leftrightarrow \ R \bowtie_A (S \bowtie_A R) \\ \Leftrightarrow \ (R \bowtie_A S) \bowtie_A (S \bowtie_A R) \end{split}$$

Semijoin Algorithms

- Perform the join
 - \blacksquare send *R* to Site 2
 - \blacksquare Site 2 computes $R \bowtie_A S$
- Consider semijoin $(R \bowtie_A S) \bowtie_A S$
 - \implies $S' \leftarrow \prod_A (S)$
 - $\implies S' \rightarrow \text{Site 1}$
 - Site 1 computes $R' = R \bowtie_A S'$
 - \implies $R' \rightarrow$ Site 2
 - \blacksquare Site 2 computes $R' \bowtie_A S$

Semijoin is better if

 $size(\Pi_{A}(S)) + size(R \bowtie_{A} S)) < size(R)$

Distributed Query Processing

Algorithms	Opt. Timing	Objective Function	Opt. Factors	Network Topology	Semijoin	Stats	Fragments
Dist. INGRES	Dynamic	Resp. time or Total time	Msg. Size, Proc. Cost	General or Broadcast	No	1	Horizontal
R*	Static	Total time	No. Msg., Msg. Size, IO, CPU	General or Local	No	1, 2	No
SDD-1	Static	Total time	Msg. Size	General	Yes	1,3,4, 5	No

1: relation cardinality; 2: number of unique values per attribute; 3: join selectivity factor; 4: size of projection on each join attribute; 5: attribute size and tuple size

Distributed INGRES Algorithm

Same as the centralized version except

- Movement of relations (and fragments) need to be considered
- Optimization with respect to communication cost or response time possible

R* Algorithm

- Cost function includes local processing as well as transmission
- Considers only joins
- Exhaustive search
- Compilation
- Published papers provide solutions to handling horizontal and vertical fragmentations but the implemented prototype does not

R* Algorithm

Performing joins

- Ship whole
 - 🗯 larger data transfer
 - smaller number of messages
 - better if relations are small
- Fetch as needed
 - number of messages = O(cardinality of external relation)
 - data transfer per message is minimal
 - better if relations are large and the selectivity is good

- 1. Move outer relation tuples to the site of the inner relation
 - (a) Retrieve outer tuples
 - (b) Send them to the inner relation site
 - (c) Join them as they arrive
 - Total Cost = cost(retrieving qualified outer tuples)

+ no. of outer tuples fetched * cost(retrieving qualified inner tuples)

+ msg. cost * (no. outer tuples fetched * avg. outer tuple size) / msg. size

- 2. Move inner relation to the site of outer relation cannot join as they arrive; they need to be stored Total Cost = cost(retrieving qualified outer tuples)
 - + no. of outer tuples fetched * cost(retrieving matching inner tuples from temporary storage)
 - + cost(retrieving qualified inner tuples)
 - + cost(storing all qualified inner tuples in temporary storage)
 - + msg. cost * (no. of inner tuples fetched * avg. inner tuple size) / msg. size

- **3**. Move both inner and outer relations to another site
 - Total cost = cost(retrieving qualified outer tuples)
 - + cost(retrieving qualified inner tuples)
 - + cost(storing inner tuples in storage)
 - + msg. cost * (no. of outer tuples fetched * avg. outer tuple size) / msg. size
 - + msg. cost * (no. of inner tuples fetched * avg. inner tuple size) / msg. size
 - + no. of outer tuples fetched * cost(retrieving inner tuples from temporary storage)

4. Fetch inner tuples as needed

- (a) Retrieve qualified tuples at outer relation site
- (b) Send request containing join column value(s) for outer tuples to inner relation site
- (c) Retrieve matching inner tuples at inner relation site
- (d) Send the matching inner tuples to outer relation site

(e) Join as they arrive

Total Cost = cost(retrieving qualified outer tuples)

- + msg. cost * (no. of outer tuples fetched)
- + no. of outer tuples fetched * (no. of inner tuples fetched * avg. inner tuple size * msg. cost / msg. size)
- + no. of outer tuples fetched * cost(retrieving matching inner tuples for one outer value)

SDD-1 Algorithm

Based on the Hill Climbing Algorithm

- Semijoins
- No replication
- No fragmentation
- Cost of transferring the result to the user site from the final result site is not considered
- Can minimize either total time or response time

Hill Climbing Algorithm

- Assume join is between three relations.
- Step 1: Do initial processing
- **Step 2**: Select initial feasible solution (ES_0)
 - 2.1 Determine the candidate result sites sites where a relation referenced in the query exist
 - 2.2 Compute the cost of transferring all the other referenced relations to each candidate site
 - 2.3 ES_0 = candidate site with minimum cost
- $\begin{array}{l} \textbf{Step 3: Determine candidate splits of } ES_0 \text{ into } \\ \{ES_1, \, ES_2\} \end{array}$
 - **3.1** ES_1 consists of sending one of the relations to the other relation's site
 - **3.2** ES_2 consists of sending the join of the relations to the final result site

Hill Climbing Algorithm

Step 4: Replace ES_0 with the split schedule which gives

 $cost(ES_1) + cost(local join) + cost(ES_2) < cost(ES_0)$

Step 5: Recursively apply steps 3–4 on ES_1 and ES_2 until no such plans can be found

Step 6: Check for redundant transmissions in the final plan and eliminate them.

What are the salaries of engineers who work on the CAD/CAM project?

 $\Pi_{\text{SAL}}(\text{PAY}\bowtie_{\text{TITLE}}(\text{EMP}\bowtie_{\text{ENO}}(\text{ASG}\bowtie_{\text{PNO}}(\sigma_{\text{PNAME}=\text{``CAD/CAM''}}(\text{PROJ})))))$

<u>Relation</u>	<u>Size</u>	Site		
EMP	8	1		
PAY	4	2		
PROJ	4	3		
ASG	10	4		

Assume:

- ➡ Size of relations is defined as their cardinality
- Minimize total cost
- Transmission cost between two sites is 1
- Ignore local processing cost

Step 1:

Selection on PROJ; result has cardinality 1

<u>Relation</u>	<u>Size</u>	Site
EMP	8	1
PAY	4	2
PROJ	1	3
ASG	10	4

Step 2: Initial feasible solution
Alternative 1: Resulting site is Site 1
Total cost = $cost(PAY \rightarrow Site 1) + cost(ASG \rightarrow Site 1) + cost(PROJ \rightarrow Site 1)$
= 4 + 10 + 1 = 15
Alternative 2: Resulting site is Site 2
Total cost = $8 + 10 + 1 = 19$
Alternative 3: Resulting site is Site 3
Total cost = $8 + 4 + 10 = 22$
Alternative 4: Resulting site is Site 4
Total cost = $8 + 4 + 1 = 13$
Therefore $ES_0 = \{ \text{EMP} \rightarrow \text{Site } 4; \text{ s} \rightarrow \text{Site } 4; \text{ proj} \rightarrow \text{Site } 4 \}$

Step 3: Determine candidate splits Alternative 1: $\{ES_1, ES_2, ES_3\}$ where ES_1 : EMP \rightarrow Site 2 ES_{2} : (EMP \bowtie PAY) \rightarrow Site 4 ES_3 : PROJ \rightarrow Site 4 Alternative 2: $\{ES_1, ES_2, ES_3\}$ where ES_1 : PAY \rightarrow Site 1 ES_2 : (PAY \bowtie EMP) \rightarrow Site 4 ES_3 : PROJ \rightarrow Site 4

Step 4: Determine costs of each split alternative

 $cost(Alternative 1) = cost(EMP \rightarrow Site 2) + cost((EMP \rightarrow QPAY) \rightarrow Site 4) + cost(PROJ \rightarrow Site 4)$

= 8 + 8 + 1 = 17

 $cost(Alternative 2) = cost(PAY \rightarrow Site 1) + cost((PAY \bowtie EMP) \rightarrow Site 4) + cost(PROJ \rightarrow Site 4)$

= 4 + 8 + 1 = 13

Decision : DO NOT SPLIT

Step 5: ES_0 is the "best".

Step 6: No redundant transmissions.

Hill Climbing Algorithm

Problems :

- Greedy algorithm → determines an initial feasible solution and iteratively tries to improve it
- If there are local minimas, it may not find global minima
- If the optimal schedule has a high initial cost, it won't find it since it won't choose it as the initial feasible solution

Example : A better schedule is

```
PROJ → Site 4
ASG' = (PROJ ⋈ASG) → Site 1
(ASG' ⋈ EMP) → Site 2
Total cost = 1 + 2 + 2 = 5
```

SDD-1 Algorithm

Initialization

- Step 1: In the execution strategy (call it ES), include all the local processing
- Step 2: Reflect the effects of local processing on the database profile
- Step 3: Construct a set of beneficial semijoin operations (*BS*) as follows :

 $BS = \emptyset$

For each semijoin SJ_i

 $BS \leftarrow BS \cup SJ_i$ if $cost(SJ_i) < benefit(SJ_i)$

SDD-1 Algorithm – Example

Consider the following query

SELECT	R3.C					
FROM	R1, R2, R3					
WHERE	R1.A = R2.A					
AND	R2.B = R3.B					

which has the following query graph and statistics:

			relation	card	tuple	size	relation size
			R1	30	50)	1500
Site 1	Site 2	Site 3	R2	100	30)	3000
Δ	── B	\frown	R3	50	40)	2000
(R1)	(R2)	-(R3)	attribu	ite	SF _K	siz	$ze(\Pi_{attribute})$
\smile			R1.A		0.3		36
		R2.A		0.8		320	
		R2.B		1.0		400	
			R3.B		0.4		80

SDD-1 Algorithm – Example

Beneficial semijoins:

- → $SJ_1 = R2 \bowtie R1$, whose benefit is 2100 = (1 - 0.3)*3000 and cost is 36
- → $SJ_2 = R2 \bowtie R3$, whose benefit is 1800 = (1 - 0.4) *3000 and cost is 80
- Nonbeneficial semijoins:
 - → $SJ_3 = R1 \Join R2$, whose benefit is 300 = (1 - 0.8) *1500 and cost is 320

 $\implies SJ_4$ = R3 \bowtie R2 , whose benefit is 0 and cost is 400

SDD-1 Algorithm

Iterative Process

- **Step 4:** Remove the most beneficial SJ_i from BS and append it to ES
- **Step 5:** Modify the database profile accordingly
- **Step 6:** Modify *BS* appropriately
 - compute new benefit/cost values
 - \blacksquare check if any new semijoin need to be included in BS

Step 7: If $BS \neq \emptyset$, go back to Step 4.

SDD-1 Algorithm – Example

- Iteration 1:
 - Remove SJ_1 from BS and add it to ES.
 - Update statistics

size(R2) = 900 (= 3000 * 0.3)

 $SF_{\geq}(R2.A) = \sim 0.8 * 0.3 = \sim 0.24$

Iteration 2:

Two beneficial semijoins:

 $SJ_2 = R2' \bowtie R3$, whose benefit is 540 = (1-0.4) *900 and cost is $200 \bowtie$

 $SJ_3 = R1$ R2', whose benefit is $1140 = (1-0.24) \times 1500$ and cost is 96

 \blacksquare Add SJ_3 to ES

Update statistics

size(R1) = 360 (= 1500*0.24) $SF^{\Join}(R1.A) = \sim 0.3*0.24 = 0.072$

SDD-1 Algorithm – Example

Iteration 3:

- ➡ No new beneficial semijoins.
- Remove remaining beneficial semijoin SJ_2 from BS and add it to ES.
- **Update statistics**

size(R2) = 360 (= 900*0.4)

Note: selectivity of R2 may also change, but not important in this example.

SDD-1 Algorithm

Assembly Site Selection

Step 8: Find the site where the largest amount of data resides and select it as the assembly site

Example:

Amount of data stored at sites:

Site 1: 360

Site 2: 360

Site 3: 2000

Therefore, Site 3 will be chosen as the assembly site.

SDD-1 Algorithm

Postprocessing

Step 9: For each R_i at the assembly site, find the semijoins of the type

 $R_i \bowtie R_j$

where the total cost of ES without this semijoin is smaller than the cost with it and remove the semijoin from ES.

Note : There might be indirect benefits.

Example: No semijoins are removed.

Step 10: Permute the order of semijoins if doing so

would improve the total cost of ES.

 ➡ Example: Final strategy: Send (R2 ⋈ R1)⋈ R3 to Site 3 Send R1 ⋈ R2 to Site 3

Step 4 – Local Optimization

Input: Best global execution schedule

- Select the best access path
- Use the centralized optimization techniques

Distributed Query Optimization Problems

Cost model

- multiple query optimization
- heuristics to cut down on alternatives
- Larger set of queries
 - optimization only on select-project-join queries
 - also need to handle complex queries (e.g., unions, disjunctions, aggregations and sorting)
- Optimization cost vs execution cost tradeoff
 - heuristics to cut down on alternatives
 - controllable search strategies
- Optimization/reoptimization interval
 - extent of changes in database profile before reoptimization is necessary
